

## Chapter 2

# Probability (special topic)

Probability forms a foundation for statistics. You might already be familiar with many aspects of probability, however, formalization of the concepts is new for most. This chapter aims to introduce probability on familiar terms using processes most people have seen before.

### 2.1 Defining probability (special topic)

- **Example 2.1** A “die”, the singular of dice, is a cube with six faces numbered 1, 2, 3, 4, 5, and 6. What is the chance of getting 1 when rolling a die?

If the die is fair, then the chance of a 1 is as good as the chance of any other number. Since there are six outcomes, the chance must be 1-in-6 or, equivalently,  $1/6$ .

- **Example 2.2** What is the chance of getting a 1 or 2 in the next roll?

1 and 2 constitute two of the six equally likely possible outcomes, so the chance of getting one of these two outcomes must be  $2/6 = 1/3$ .

- **Example 2.3** What is the chance of getting either 1, 2, 3, 4, 5, or 6 on the next roll?

100%. The outcome must be one of these numbers.

- **Example 2.4** What is the chance of not rolling a 2?

Since the chance of rolling a 2 is  $1/6$  or  $16.\bar{6}\%$ , the chance of not rolling a 2 must be  $100\% - 16.\bar{6}\% = 83.\bar{3}\%$  or  $5/6$ .

Alternatively, we could have noticed that not rolling a 2 is the same as getting a 1, 3, 4, 5, or 6, which makes up five of the six equally likely outcomes and has probability  $5/6$ .

- **Example 2.5** Consider rolling two dice. If  $1/6^{th}$  of the time the first die is a 1 and  $1/6^{th}$  of those times the second die is a 1, what is the chance of getting two 1s?

If  $16.\bar{6}\%$  of the time the first die is a 1 and  $1/6^{th}$  of *those* times the second die is also a 1, then the chance that both dice are 1 is  $(1/6) \times (1/6)$  or  $1/36$ .

Figure 2.1: The fraction of die rolls that are 1 at each stage in a simulation. The proportion tends to get closer to the probability  $1/6 \approx 0.167$  as the number of rolls increases.

### 2.1.1 Probability

We use probability to build tools to describe and understand apparent randomness. We often frame probability in terms of a **random process** giving rise to an **outcome**.

Roll a die  $\rightarrow$  1, 2, 3, 4, 5, or 6  
 Flip a coin  $\rightarrow$  H or T

Rolling a die or flipping a coin is a seemingly random process and each gives rise to an outcome.

#### Probability

The **probability** of an outcome is the proportion of times the outcome would occur if we observed the random process an infinite number of times.

Probability is defined as a proportion, and it always takes values between 0 and 1 (inclusively). It may also be displayed as a percentage between 0% and 100%.

Probability can be illustrated by rolling a die many times. Let  $\hat{p}_n$  be the proportion of outcomes that are 1 after the first  $n$  rolls. As the number of rolls increases,  $\hat{p}_n$  will converge to the probability of rolling a 1,  $p = 1/6$ . Figure 2.1 shows this convergence for 100,000 die rolls. The tendency of  $\hat{p}_n$  to stabilize around  $p$  is described by the **Law of Large Numbers**.

#### Law of Large Numbers

As more observations are collected, the proportion  $\hat{p}_n$  of occurrences with a particular outcome converges to the probability  $p$  of that outcome.

Occasionally the proportion will veer off from the probability and appear to defy the Law of Large Numbers, as  $\hat{p}_n$  does many times in Figure 2.1. However, these deviations become smaller as the number of rolls increases.

Above we write  $p$  as the probability of rolling a 1. We can also write this probability as

$P(A)$   
Probability of  
outcome  $A$

$P(\text{rolling a 1})$

As we become more comfortable with this notation, we will abbreviate it further. For instance, if it is clear that the process is “rolling a die”, we could abbreviate  $P(\text{rolling a 1})$  as  $P(1)$ .

- ⦿ **Exercise 2.6** Random processes include rolling a die and flipping a coin. (a) Think of another random process. (b) Describe all the possible outcomes of that process. For instance, rolling a die is a random process with potential outcomes 1, 2, ..., 6.<sup>1</sup>

What we think of as random processes are not necessarily random, but they may just be too difficult to understand exactly. The fourth example in the footnote solution to Exercise 2.6 suggests a roommate’s behavior is a random process. However, even if a roommate’s behavior is not truly random, modeling her behavior as a random process can still be useful.

**TIP: Modeling a process as random**

It can be helpful to model a process as random even if it is not truly random.

### 2.1.2 Disjoint or mutually exclusive outcomes

Two outcomes are called **disjoint** or **mutually exclusive** if they cannot both happen. For instance, if we roll a die, the outcomes 1 and 2 are disjoint since they cannot both occur. On the other hand, the outcomes 1 and “rolling an odd number” are not disjoint since both occur if the outcome of the roll is a 1. The terms *disjoint* and *mutually exclusive* are equivalent and interchangeable.

Calculating the probability of disjoint outcomes is easy. When rolling a die, the outcomes 1 and 2 are disjoint, and we compute the probability that one of these outcomes will occur by adding their separate probabilities:

$$P(1 \text{ or } 2) = P(1) + P(2) = 1/6 + 1/6 = 1/3$$

What about the probability of rolling a 1, 2, 3, 4, 5, or 6? Here again, all of the outcomes are disjoint so we add the probabilities:

$$\begin{aligned} P(1 \text{ or } 2 \text{ or } 3 \text{ or } 4 \text{ or } 5 \text{ or } 6) \\ &= P(1) + P(2) + P(3) + P(4) + P(5) + P(6) \\ &= 1/6 + 1/6 + 1/6 + 1/6 + 1/6 + 1/6 = 1. \end{aligned}$$

The **Addition Rule** guarantees the accuracy of this approach when the outcomes are disjoint.

<sup>1</sup>Here are four examples. (i) Whether someone gets sick in the next month or not is an apparently random process with outcomes **sick** and **not**. (ii) We can *generate* a random process by randomly picking a person and measuring that person’s height. The outcome of this process will be a positive number. (iii) Whether the stock market goes up or down next week is a seemingly random process with possible outcomes **up**, **down**, and **no\_change**. Alternatively, we could have used the percent change in the stock market as a numerical outcome. (iv) Whether your roommate cleans her dishes tonight probably seems like a random process with possible outcomes **cleans\_dishes** and **leaves\_dishes**.

**Addition Rule of disjoint outcomes**

If  $A_1$  and  $A_2$  represent two disjoint outcomes, then the probability that one of them occurs is given by

$$P(A_1 \text{ or } A_2) = P(A_1) + P(A_2)$$

If there are many disjoint outcomes  $A_1, \dots, A_k$ , then the probability that one of these outcomes will occur is

$$P(A_1) + P(A_2) + \dots + P(A_k) \quad (2.7)$$

- **Exercise 2.8** We are interested in the probability of rolling a 1, 4, or 5. (a) Explain why the outcomes 1, 4, and 5 are disjoint. (b) Apply the Addition Rule for disjoint outcomes to determine  $P(1 \text{ or } 4 \text{ or } 5)$ .<sup>2</sup>

- **Exercise 2.9** In the `email` data set in Chapter 1, the `number` variable described whether no number (labeled `none`), only one or more small numbers (`small`), or whether at least one big number appeared in an email (`big`). Of the 3,921 emails, 549 had no numbers, 2,827 had only one or more small numbers, and 545 had at least one big number. (a) Are the outcomes `none`, `small`, and `big` disjoint? (b) Determine the proportion of emails with value `small` and `big` separately. (c) Use the Addition Rule for disjoint outcomes to compute the probability a randomly selected email from the data set has a number in it, small or big.<sup>3</sup>

Statisticians rarely work with individual outcomes and instead consider *sets* or *collections* of outcomes. Let  $A$  represent the event where a die roll results in 1 or 2 and  $B$  represent the event that the die roll is a 4 or a 6. We write  $A$  as the set of outcomes  $\{1, 2\}$  and  $B = \{4, 6\}$ . These sets are commonly called **events**. Because  $A$  and  $B$  have no elements in common, they are disjoint events.  $A$  and  $B$  are represented in Figure 2.2.

Figure 2.2: Three events,  $A$ ,  $B$ , and  $D$ , consist of outcomes from rolling a die.  $A$  and  $B$  are disjoint since they do not have any outcomes in common.

The Addition Rule applies to both disjoint outcomes and disjoint events. The probability that one of the disjoint events  $A$  or  $B$  occurs is the sum of the separate probabilities:

$$P(A \text{ or } B) = P(A) + P(B) = 1/3 + 1/3 = 2/3$$

- **Exercise 2.10** (a) Verify the probability of event  $A$ ,  $P(A)$ , is  $1/3$  using the Addition Rule. (b) Do the same for event  $B$ .<sup>4</sup>

<sup>2</sup>(a) The random process is a die roll, and at most one of these outcomes can come up. This means they are disjoint outcomes. (b)  $P(1 \text{ or } 4 \text{ or } 5) = P(1) + P(4) + P(5) = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{3}{6} = \frac{1}{2}$

<sup>3</sup>(a) Yes. Each email is categorized in only one level of `number`. (b) Small:  $\frac{2827}{3921} = 0.721$ . Big:  $\frac{545}{3921} = 0.139$ . (c)  $P(\text{small or big}) = P(\text{small}) + P(\text{big}) = 0.721 + 0.139 = 0.860$ .

<sup>4</sup>(a)  $P(A) = P(1 \text{ or } 2) = P(1) + P(2) = \frac{1}{6} + \frac{1}{6} = \frac{2}{6} = \frac{1}{3}$ . (b) Similarly,  $P(B) = 1/3$ .

2♣	3♣	4♣	5♣	6♣	7♣	8♣	9♣	10♣	J♣	Q♣	K♣	A♣
2♦	3♦	4♦	5♦	6♦	7♦	8♦	9♦	10♦	J♦	Q♦	K♦	A♦
2♥	3♥	4♥	5♥	6♥	7♥	8♥	9♥	10♥	J♥	Q♥	K♥	A♥
2♠	3♠	4♠	5♠	6♠	7♠	8♠	9♠	10♠	J♠	Q♠	K♠	A♠

Table 2.3: Representations of the 52 unique cards in a deck.

- ⊙ **Exercise 2.11** (a) Using Figure 2.2 as a reference, what outcomes are represented by event  $D$ ? (b) Are events  $B$  and  $D$  disjoint? (c) Are events  $A$  and  $D$  disjoint?<sup>5</sup>
- ⊙ **Exercise 2.12** In Exercise 2.11, you confirmed  $B$  and  $D$  from Figure 2.2 are disjoint. Compute the probability that either event  $B$  or event  $D$  occurs.<sup>6</sup>

### 2.1.3 Probabilities when events are not disjoint

Let's consider calculations for two events that are not disjoint in the context of a regular deck of 52 cards, represented in Table 2.3. If you are unfamiliar with the cards in a regular deck, please see the footnote.<sup>7</sup>

- ⊙ **Exercise 2.13** (a) What is the probability that a randomly selected card is a diamond? (b) What is the probability that a randomly selected card is a face card?<sup>8</sup>

**Venn diagrams** are useful when outcomes can be categorized as “in” or “out” for two or three variables, attributes, or random processes. The Venn diagram in Figure 2.4 uses a circle to represent diamonds and another to represent face cards. If a card is both a diamond and a face card, it falls into the intersection of the circles. If it is a diamond but not a face card, it will be in part of the left circle that is not in the right circle (and so on). The total number of cards that are diamonds is given by the total number of cards in the diamonds circle:  $10 + 3 = 13$ . The **probabilities** are also shown (e.g.  $10/52 = 0.1923$ ).

- ⊙ **Exercise 2.14** Using the Venn diagram, verify  $P(\text{face card}) = 12/52 = 3/13$ .<sup>9</sup>

Let  $A$  represent the event that a randomly selected card is a diamond and  $B$  represent the event that it is a face card. How do we compute  $P(A \text{ or } B)$ ? Events  $A$  and  $B$  are not disjoint – the cards  $J♦$ ,  $Q♦$ , and  $K♦$  fall into both categories – so we cannot use the

<sup>5</sup>(a) Outcomes 2 and 3. (b) Yes, events  $B$  and  $D$  are disjoint because they share no outcomes. (c) The events  $A$  and  $D$  share an outcome in common, 2, and so are not disjoint.

<sup>6</sup>Since  $B$  and  $D$  are disjoint events, use the Addition Rule:  $P(B \text{ or } D) = P(B) + P(D) = \frac{1}{3} + \frac{1}{3} = \frac{2}{3}$ .

<sup>7</sup>The 52 cards are split into four **suits**: ♣ (club), ♦ (diamond), ♥ (heart), ♠ (spade). Each suit has its 13 cards labeled: 2, 3, ..., 10, J (jack), Q (queen), K (king), and A (ace). Thus, each card is a unique combination of a suit and a label, e.g.  $4♥$  and  $J♣$ . The 12 cards represented by the jacks, queens, and kings are called **face cards**. The cards that are ♦ or ♥ are typically colored **red** while the other two suits are typically colored **black**.

<sup>8</sup>(a) There are 52 cards and 13 diamonds. If the cards are thoroughly shuffled, each card has an equal chance of being drawn, so the probability that a randomly selected card is a diamond is  $P(♦) = \frac{13}{52} = 0.250$ .

(b) Likewise, there are 12 face cards, so  $P(\text{face card}) = \frac{12}{52} = \frac{3}{13} = 0.231$ .

<sup>9</sup>The Venn diagram shows face cards split up into “face card but not ♦” and “face card and ♦”. Since these correspond to disjoint events,  $P(\text{face card})$  is found by adding the two corresponding probabilities:  $\frac{3}{52} + \frac{9}{52} = \frac{12}{52} = \frac{3}{13}$ .

Figure 2.4: A Venn diagram for diamonds and face cards.

Addition Rule for disjoint events. Instead we use the Venn diagram. We start by adding the probabilities of the two events:

$$P(A) + P(B) = P(\diamond) + P(\text{face card}) = 12/52 + 13/52$$

However, the three cards that are in both events were counted twice, once in each probability. We must correct this double counting:

$$\begin{aligned} P(A \text{ or } B) &= P(\text{face card or } \diamond) \\ &= P(\text{face card}) + P(\diamond) - P(\text{face card and } \diamond) \\ &= 12/52 + 13/52 - 3/52 \\ &= 22/52 = 11/26 \end{aligned} \tag{2.15}$$

Equation (2.15) is an example of the **General Addition Rule**.

#### General Addition Rule

If  $A$  and  $B$  are any two events, disjoint or not, then the probability that at least one of them will occur is

$$P(A \text{ or } B) = P(A) + P(B) - P(A \text{ and } B) \tag{2.16}$$

where  $P(A \text{ and } B)$  is the probability that both events occur.

#### TIP: “or” is inclusive

When we write “or” in statistics, we mean “and/or” unless we explicitly state otherwise. Thus,  $A$  or  $B$  occurs means  $A$ ,  $B$ , or both  $A$  and  $B$  occur.

- ⊙ **Exercise 2.17** (a) If  $A$  and  $B$  are disjoint, describe why this implies  $P(A \text{ and } B) = 0$ . (b) Using part (a), verify that the General Addition Rule simplifies to the simpler Addition Rule for disjoint events if  $A$  and  $B$  are disjoint.<sup>10</sup>

<sup>10</sup>(a) If  $A$  and  $B$  are disjoint,  $A$  and  $B$  can never occur simultaneously. (b) If  $A$  and  $B$  are disjoint, then the last term of Equation (2.16) is 0 (see part (a)) and we are left with the Addition Rule for disjoint events.

- ⊙ **Exercise 2.18** In the `email` data set with 3,921 emails, 367 were spam, 2,827 contained some small numbers but no big numbers, and 168 had both characteristics. Create a Venn diagram for this setup.<sup>11</sup>
- ⊙ **Exercise 2.19** (a) Use your Venn diagram from Exercise 2.18 to determine the probability a randomly drawn email from the `email` data set is spam and had small numbers (but not big numbers). (b) What is the probability that the email had either of these attributes?<sup>12</sup>

### 2.1.4 Probability distributions

A **probability distribution** is a table of all disjoint outcomes and their associated probabilities. Table 2.5 shows the probability distribution for the sum of two dice.

Dice sum	2	3	4	5	6	7	8	9	10	11	12
Probability	$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

Table 2.5: Probability distribution for the sum of two dice.

#### Rules for probability distributions

A probability distribution is a list of the possible outcomes with corresponding probabilities that satisfies three rules:

1. The outcomes listed must be disjoint.
2. Each probability must be between 0 and 1.
3. The probabilities must total 1.

- ⊙ **Exercise 2.20** Table 2.6 suggests three distributions for household income in the United States. Only one is correct. Which one must it be? What is wrong with the other two?<sup>13</sup>

Chapter 1 emphasized the importance of plotting data to provide quick summaries. Probability distributions can also be summarized in a bar plot. For instance, the distribution of US household incomes is shown in Figure 2.7 as a bar plot.<sup>14</sup> The probability distribution for the sum of two dice is shown in Table 2.5 and plotted in Figure 2.8.

In these bar plots, the bar heights represent the probabilities of outcomes. If the outcomes are numerical and discrete, it is usually (visually) convenient to make a bar plot that resembles a histogram, as in the case of the sum of two dice. Another example of plotting the bars at their respective locations is shown in Figure 2.20 on page 96.

<sup>11</sup>Both the counts and corresponding **probabilities** (e.g.  $2659/3921 = 0.678$ ) are shown. Notice that the number of emails represented in the left circle corresponds to  $2659 + 168 = 2827$ , and the number represented in the right circle is  $168 + 199 = 367$ .

<sup>12</sup>(a) The solution is represented by the intersection of the two circles:  $0.043$ . (b) This is the sum of the three disjoint probabilities shown in the circles:  $0.678 + 0.043 + 0.051 = 0.772$ .

<sup>13</sup>The probabilities of (a) do not sum to 1. The second probability in (b) is negative. This leaves (c), which sure enough satisfies the requirements of a distribution. One of the three was said to be the actual distribution of US household incomes, so it must be (c).

<sup>14</sup>It is also possible to construct a distribution plot when income is not artificially binned into four groups. *Continuous* distributions are considered in Section 2.5.

Income range (\$1000s)	0-25	25-50	50-100	100+
(a)	0.18	0.39	0.33	0.16
(b)	0.38	-0.27	0.52	0.37
(c)	0.28	0.27	0.29	0.16

Table 2.6: Proposed distributions of US household incomes (Exercise 2.20).

Figure 2.7: The probability distribution of US household income.

Figure 2.8: The probability distribution of the sum of two dice.

### 2.1.5 Complement of an event

$S$   
Sample space

Rolling a die produces a value in the set  $\{1, 2, 3, 4, 5, 6\}$ . This set of all possible outcomes is called the **sample space** ( $S$ ) for rolling a die. We often use the sample space to examine the scenario where an event does not occur.

$A^c$   
Complement  
of outcome  $A$

Let  $D = \{2, 3\}$  represent the event that the outcome of a die roll is 2 or 3. Then the **complement** of  $D$  represents all outcomes in our sample space that are not in  $D$ , which is denoted by  $D^c = \{1, 4, 5, 6\}$ . That is,  $D^c$  is the set of all possible outcomes not already included in  $D$ . Figure 2.9 shows the relationship between  $D$ ,  $D^c$ , and the sample space  $S$ .

Figure 2.9: Event  $D = \{2, 3\}$  and its complement,  $D^c = \{1, 4, 5, 6\}$ .  $S$  represents the sample space, which is the set of all possible events.

⊙ **Exercise 2.21** (a) Compute  $P(D^c) = P(\text{rolling a 1, 4, 5, or 6})$ . (b) What is  $P(D) + P(D^c)$ ?<sup>15</sup>

⊙ **Exercise 2.22** Events  $A = \{1, 2\}$  and  $B = \{4, 6\}$  are shown in Figure 2.2 on page 71. (a) Write out what  $A^c$  and  $B^c$  represent. (b) Compute  $P(A^c)$  and  $P(B^c)$ . (c) Compute  $P(A) + P(A^c)$  and  $P(B) + P(B^c)$ .<sup>16</sup>

A complement of an event  $A$  is constructed to have two very important properties: (i) every possible outcome not in  $A$  is in  $A^c$ , and (ii)  $A$  and  $A^c$  are disjoint. Property (i) implies

$$P(A \text{ or } A^c) = 1 \quad (2.23)$$

That is, if the outcome is not in  $A$ , it must be represented in  $A^c$ . We use the Addition Rule for disjoint events to apply Property (ii):

$$P(A \text{ or } A^c) = P(A) + P(A^c) \quad (2.24)$$

Combining Equations (2.23) and (2.24) yields a very useful relationship between the probability of an event and its complement.

#### Complement

The complement of event  $A$  is denoted  $A^c$ , and  $A^c$  represents all outcomes not in  $A$ .  $A$  and  $A^c$  are mathematically related:

$$P(A) + P(A^c) = 1, \quad \text{i.e.} \quad P(A) = 1 - P(A^c) \quad (2.25)$$

In simple examples, computing  $A$  or  $A^c$  is feasible in a few steps. However, using the complement can save a lot of time as problems grow in complexity.

<sup>15</sup>(a) The outcomes are disjoint and each has probability  $1/6$ , so the total probability is  $4/6 = 2/3$ . (b) We can also see that  $P(D) = \frac{1}{6} + \frac{1}{6} = 1/3$ . Since  $D$  and  $D^c$  are disjoint,  $P(D) + P(D^c) = 1$ .

<sup>16</sup>Brief solutions: (a)  $A^c = \{3, 4, 5, 6\}$  and  $B^c = \{1, 2, 3, 5\}$ . (b) Noting that each outcome is disjoint, add the individual outcome probabilities to get  $P(A^c) = 2/3$  and  $P(B^c) = 2/3$ . (c)  $A$  and  $A^c$  are disjoint, and the same is true of  $B$  and  $B^c$ . Therefore,  $P(A) + P(A^c) = 1$  and  $P(B) + P(B^c) = 1$ .

⊙ **Exercise 2.26** Let  $A$  represent the event where we roll two dice and their total is less than 12. (a) What does the event  $A^c$  represent? (b) Determine  $P(A^c)$  from Table 2.5 on page 74. (c) Determine  $P(A)$ .<sup>17</sup>

⊙ **Exercise 2.27** Consider again the probabilities from Table 2.5 and rolling two dice. Find the following probabilities: (a) The sum of the dice is *not* 6. (b) The sum is at least 4. That is, determine the probability of the event  $B = \{4, 5, \dots, 12\}$ . (c) The sum is no more than 10. That is, determine the probability of the event  $D = \{2, 3, \dots, 10\}$ .<sup>18</sup>

### 2.1.6 Independence

Just as variables and observations can be independent, random processes can be independent, too. Two processes are **independent** if knowing the outcome of one provides no useful information about the outcome of the other. For instance, flipping a coin and rolling a die are two independent processes – knowing the coin was heads does not help determine the outcome of a die roll. On the other hand, stock prices usually move up or down together, so they are not independent.

Example 2.5 provides a basic example of two independent processes: rolling two dice. We want to determine the probability that both will be 1. Suppose one of the dice is red and the other white. If the outcome of the red die is a 1, it provides no information about the outcome of the white die. We first encountered this same question in Example 2.5 (page 68), where we calculated the probability using the following reasoning:  $1/6^{th}$  of the time the red die is a 1, and  $1/6^{th}$  of *those* times the white die will also be 1. This is illustrated in Figure 2.10. Because the rolls are independent, the probabilities of the corresponding outcomes can be multiplied to get the final answer:  $(1/6) \times (1/6) = 1/36$ . This can be generalized to many independent processes.

Figure 2.10:  $1/6^{th}$  of the time, the first roll is a 1. Then  $1/6^{th}$  of *those* times, the second roll will also be a 1.

<sup>17</sup>(a) The complement of  $A$ : when the total is equal to 12. (b)  $P(A^c) = 1/36$ . (c) Use the probability of the complement from part (b),  $P(A^c) = 1/36$ , and Equation (2.25):  $P(\text{less than } 12) = 1 - P(12) = 1 - 1/36 = 35/36$ .

<sup>18</sup>(a) First find  $P(6) = 5/36$ , then use the complement:  $P(\text{not } 6) = 1 - P(6) = 31/36$ .

(b) First find the complement, which requires much less effort:  $P(2 \text{ or } 3) = 1/36 + 2/36 = 1/12$ . Then calculate  $P(B) = 1 - P(B^c) = 1 - 1/12 = 11/12$ .

(c) As before, finding the complement is the clever way to determine  $P(D)$ . First find  $P(D^c) = P(11 \text{ or } 12) = 2/36 + 1/36 = 1/12$ . Then calculate  $P(D) = 1 - P(D^c) = 11/12$ .

- **Example 2.28** What if there was also a blue die independent of the other two? What is the probability of rolling the three dice and getting all 1s?

The same logic applies from Example 2.5. If  $1/36^{th}$  of the time the white and red dice are both 1, then  $1/6^{th}$  of *those* times the blue die will also be 1, so multiply:

$$\begin{aligned} P(\text{white} = 1 \text{ and } \text{red} = 1 \text{ and } \text{blue} = 1) &= P(\text{white} = 1) \times P(\text{red} = 1) \times P(\text{blue} = 1) \\ &= (1/6) \times (1/6) \times (1/6) = 1/216 \end{aligned}$$

Examples 2.5 and 2.28 illustrate what is called the Multiplication Rule for independent processes.

**Multiplication Rule for independent processes**

If  $A$  and  $B$  represent events from two different and independent processes, then the probability that both  $A$  and  $B$  occur can be calculated as the product of their separate probabilities:

$$P(A \text{ and } B) = P(A) \times P(B) \quad (2.29)$$

Similarly, if there are  $k$  events  $A_1, \dots, A_k$  from  $k$  independent processes, then the probability they all occur is

$$P(A_1) \times P(A_2) \times \dots \times P(A_k)$$

- ⊙ **Exercise 2.30** About 9% of people are left-handed. Suppose 2 people are selected at random from the U.S. population. Because the sample size of 2 is very small relative to the population, it is reasonable to assume these two people are independent. (a) What is the probability that both are left-handed? (b) What is the probability that both are right-handed?<sup>19</sup>
- ⊙ **Exercise 2.31** Suppose 5 people are selected at random.<sup>20</sup>
- What is the probability that all are right-handed?
  - What is the probability that all are left-handed?
  - What is the probability that not all of the people are right-handed?

<sup>19</sup>(a) The probability the first person is left-handed is 0.09, which is the same for the second person. We apply the Multiplication Rule for independent processes to determine the probability that both will be left-handed:  $0.09 \times 0.09 = 0.0081$ .

(b) It is reasonable to assume the proportion of people who are ambidextrous (both right and left handed) is nearly 0, which results in  $P(\text{right-handed}) = 1 - 0.09 = 0.91$ . Using the same reasoning as in part (a), the probability that both will be right-handed is  $0.91 \times 0.91 = 0.8281$ .

<sup>20</sup>(a) The abbreviations RH and LH are used for right-handed and left-handed, respectively. Since each are independent, we apply the Multiplication Rule for independent processes:

$$\begin{aligned} P(\text{all five are RH}) &= P(\text{first} = \text{RH}, \text{second} = \text{RH}, \dots, \text{fifth} = \text{RH}) \\ &= P(\text{first} = \text{RH}) \times P(\text{second} = \text{RH}) \times \dots \times P(\text{fifth} = \text{RH}) \\ &= 0.91 \times 0.91 \times 0.91 \times 0.91 \times 0.91 = 0.624 \end{aligned}$$

(b) Using the same reasoning as in (a),  $0.09 \times 0.09 \times 0.09 \times 0.09 \times 0.09 = 0.0000059$

(c) Use the complement,  $P(\text{all five are RH})$ , to answer this question:

$$P(\text{not all RH}) = 1 - P(\text{all RH}) = 1 - 0.624 = 0.376$$

Suppose the variables **handedness** and **gender** are independent, i.e. knowing someone's **gender** provides no useful information about their **handedness** and vice-versa. Then we can compute whether a randomly selected person is right-handed and female<sup>21</sup> using the Multiplication Rule:

$$\begin{aligned} P(\text{right-handed and female}) &= P(\text{right-handed}) \times P(\text{female}) \\ &= 0.91 \times 0.50 = 0.455 \end{aligned}$$

⊙ **Exercise 2.32** Three people are selected at random.<sup>22</sup>

- What is the probability that the first person is male and right-handed?
- What is the probability that the first two people are male and right-handed?
- What is the probability that the third person is female and left-handed?
- What is the probability that the first two people are male and right-handed and the third person is female and left-handed?

Sometimes we wonder if one outcome provides useful information about another outcome. The question we are asking is, are the occurrences of the two events independent? We say that two events  $A$  and  $B$  are independent if they satisfy Equation (2.29).

● **Example 2.33** If we shuffle up a deck of cards and draw one, is the event that the card is a heart independent of the event that the card is an ace?

The probability the card is a heart is  $1/4$  and the probability that it is an ace is  $1/13$ . The probability the card is the ace of hearts is  $1/52$ . We check whether Equation 2.29 is satisfied:

$$P(\heartsuit) \times P(\text{ace}) = \frac{1}{4} \times \frac{1}{13} = \frac{1}{52} = P(\heartsuit \text{ and ace})$$

Because the equation holds, the event that the card is a heart and the event that the card is an ace are independent events.

## 2.2 Conditional probability (special topic)

Are students more likely to use marijuana when their parents used drugs? The **drug\_use** data set contains a sample of 445 cases with two variables, **student** and **parents**, and is summarized in Table 2.11.<sup>23</sup> The **student** variable is either **uses** or **not**, where a student is labeled as **uses** if she has recently used marijuana. The **parents** variable takes the value **used** if at least one of the parents used drugs, including alcohol.

● **Example 2.34** If at least one parent used drugs, what is the chance their child (**student**) uses?

We will estimate this probability using the data. Of the 210 cases in this data set where **parents** = **used**, 125 represent cases where **student** = **uses**:

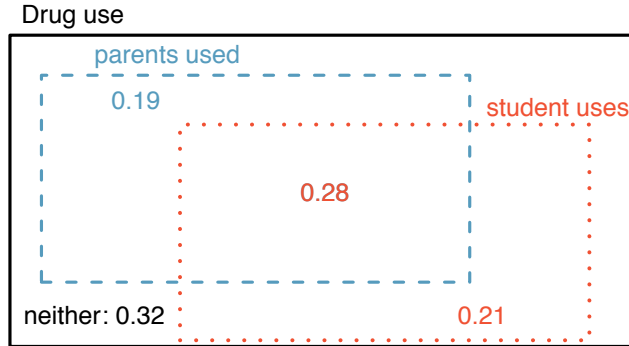

$$P(\text{student} = \text{uses given parents} = \text{used}) = \frac{125}{210} = 0.60$$

<sup>21</sup>The actual proportion of the U.S. population that is **female** is about 50%, and so we use 0.5 for the probability of sampling a woman. However, this probability does differ in other countries.

<sup>22</sup>Brief answers are provided. (a) This can be written in probability notation as  $P(\text{a randomly selected person is male and right-handed}) = 0.455$ . (b) 0.207. (c) 0.045. (d) 0.0093.

<sup>23</sup>Ellis GJ and Stone LH. 1979. Marijuana Use in College: An Evaluation of a Modeling Explanation. Youth and Society 10:323-334.

		parents		Total
		used	not	
student	uses	125	94	219
	not	85	141	226
	Total	210	235	445

Table 2.11: Contingency table summarizing the `drug_use` data set.Figure 2.12: A Venn diagram using boxes for the `drug_use` data set.

● **Example 2.35** A student is randomly selected from the study and she does not use drugs. What is the probability that at least one of her parents used?

If the student does not use drugs, then she is one of the 226 students in the second row. Of these 226 students, 85 had at least one parent who used drugs:

$$P(\text{parents} = \text{used} \text{ given } \text{student} = \text{not}) = \frac{85}{226} = 0.376$$

### 2.2.1 Marginal and joint probabilities

Table 2.13 includes row and column totals for each variable separately in the `drug_use` data set. These totals represent **marginal probabilities** for the sample, which are the probabilities based on a single variable without conditioning on any other variables. For instance, a probability based solely on the `student` variable is a marginal probability:

$$P(\text{student} = \text{uses}) = \frac{219}{445} = 0.492$$

A probability of outcomes for two or more variables or processes is called a **joint probability**:

$$P(\text{student} = \text{uses and parents} = \text{not}) = \frac{94}{445} = 0.21$$

It is common to substitute a comma for “and” in a joint probability, although either is acceptable.

	parents: used	parents: not	Total
student: uses	0.28	0.21	0.49
student: not	0.19	0.32	0.51
Total	0.47	0.53	1.00

Table 2.13: Probability table summarizing parental and student drug use.

Joint outcome	Probability
parents = used, student = uses	0.28
parents = used, student = not	0.19
parents = not, student = uses	0.21
parents = not, student = not	0.32
Total	1.00

Table 2.14: A joint probability distribution for the `drug_use` data set.

### Marginal and joint probabilities

If a probability is based on a single variable, it is a *marginal probability*. The probability of outcomes for two or more variables or processes is called a *joint probability*.

We use **table proportions** to summarize joint probabilities for the `drug_use` sample. These proportions are computed by dividing each count in Table 2.11 by 445 to obtain the proportions in Table 2.13. The joint probability distribution of the `parents` and `student` variables is shown in Table 2.14.

- ⊙ **Exercise 2.36** Verify Table 2.14 represents a probability distribution: events are disjoint, all probabilities are non-negative, and the probabilities sum to 1.<sup>24</sup>

We can compute marginal probabilities using joint probabilities in simple cases. For example, the probability a random student from the study uses drugs is found by summing the outcomes from Table 2.14 where `student = uses`:

$$\begin{aligned}
 P(\text{student} = \text{uses}) &= P(\text{parents} = \text{used}, \text{student} = \text{uses}) + \\
 &\quad P(\text{parents} = \text{not}, \text{student} = \text{uses}) \\
 &= 0.28 + 0.21 = 0.49
 \end{aligned}$$

## 2.2.2 Defining conditional probability

There is some connection between drug use of parents and of the student: drug use of one is associated with drug use of the other.<sup>25</sup> In this section, we discuss how to use information about associations between two variables to improve probability estimation.

The probability that a random student from the study uses drugs is 0.49. Could we update this probability if we knew that this student's parents used drugs? Absolutely. To

<sup>24</sup>Each of the four outcome combination are disjoint, all probabilities are indeed non-negative, and the sum of the probabilities is  $0.28 + 0.19 + 0.21 + 0.32 = 1.00$ .

<sup>25</sup>This is an observational study and no causal conclusions may be reached.

do so, we limit our view to only those 210 cases where parents used drugs and look at the fraction where the student uses drugs:

$$P(\text{student} = \text{uses given parents} = \text{used}) = \frac{125}{210} = 0.60$$

We call this a **conditional probability** because we computed the probability under a condition: **parents = used**. There are two parts to a conditional probability, **the outcome of interest** and the **condition**. It is useful to think of the condition as information we know to be true, and this information usually can be described as a known outcome or event.

We separate the text inside our probability notation into the outcome of interest and the condition:

$$\begin{aligned} P(\text{student} = \text{uses given parents} = \text{used}) \\ = P(\text{student} = \text{uses} \mid \text{parents} = \text{used}) = \frac{125}{210} = 0.60 \end{aligned} \quad (2.37)$$

$P(A|B)$

Probability of  
outcome  $A$   
given  $B$

The vertical bar “ $\mid$ ” is read as *given*.

In Equation (2.37), we computed the probability a student uses based on the condition that at least one parent used as a fraction:

$$\begin{aligned} P(\text{student} = \text{uses} \mid \text{parents} = \text{used}) \\ = \frac{\# \text{ times } \text{student} = \text{uses and } \text{parents} = \text{used}}{\# \text{ times } \text{parents} = \text{used}} \\ = \frac{125}{210} = 0.60 \end{aligned} \quad (2.38)$$

We considered only those cases that met the condition, **parents = used**, and then we computed the ratio of those cases that satisfied our outcome of interest, the student uses.

Counts are not always available for data, and instead only marginal and joint probabilities may be provided. For example, disease rates are commonly listed in percentages rather than in a count format. We would like to be able to compute conditional probabilities even when no counts are available, and we use Equation (2.38) as an example demonstrating this technique.

We considered only those cases that satisfied the condition, **parents = used**. Of these cases, the conditional probability was the fraction who represented the outcome of interest, **student = uses**. Suppose we were provided only the information in Table 2.13 on the preceding page, i.e. only probability data. Then if we took a sample of 1000 people, we would anticipate about 47% or  $0.47 \times 1000 = 470$  would meet our information criterion. Similarly, we would expect about 28% or  $0.28 \times 1000 = 280$  to meet both the information criterion and represent our outcome of interest. Thus, the conditional probability could be computed:

$$\begin{aligned} P(\text{student} = \text{uses} \mid \text{parents} = \text{used}) &= \frac{\# (\text{student} = \text{uses and } \text{parents} = \text{used})}{\# (\text{parents} = \text{used})} \\ &= \frac{280}{470} = \frac{0.28}{0.47} = 0.60 \end{aligned} \quad (2.39)$$

In Equation (2.39), we examine exactly the fraction of two probabilities, 0.28 and 0.47, which we can write as

$$P(\text{student} = \text{uses and } \text{parents} = \text{used}) \quad \text{and} \quad P(\text{parents} = \text{used}).$$

The fraction of these probabilities represents our general formula for conditional probability.

**Conditional Probability**

The conditional probability of the outcome of interest  $A$  given condition  $B$  is computed as the following:

$$P(A|B) = \frac{P(A \text{ and } B)}{P(B)} \quad (2.40)$$

- ⊙ **Exercise 2.41** (a) Write out the following statement in conditional probability notation: “The probability a random case has **parents = not** if it is known that **student = not**”. Notice that the condition is now based on the student, not the parent. (b) Determine the probability from part (a). Table 2.13 on page 81 may be helpful.<sup>26</sup>

- ⊙ **Exercise 2.42** (a) Determine the probability that one of the parents had used drugs if it is known the student does not use drugs. (b) Using the answers from part (a) and Exercise 2.41(b), compute

$$P(\text{parents} = \text{used} | \text{student} = \text{not}) + P(\text{parents} = \text{not} | \text{student} = \text{not})$$

- (c) Provide an intuitive argument to explain why the sum in (b) is 1.<sup>27</sup>

- ⊙ **Exercise 2.43** The data indicate that drug use of parents and children are associated. Does this mean the drug use of parents causes the drug use of the students?<sup>28</sup>

**2.2.3 Smallpox in Boston, 1721**

The `smallpox` data set provides a sample of 6,224 individuals from the year 1721 who were exposed to smallpox in Boston.<sup>29</sup> Doctors at the time believed that inoculation, which involves exposing a person to the disease in a controlled form, could reduce the likelihood of death.

Each case represents one person with two variables: `inoculated` and `result`. The variable `inoculated` takes two levels: `yes` or `no`, indicating whether the person was inoculated or not. The variable `result` has outcomes `lived` or `died`. These data are summarized in Tables 2.15 and 2.16.

- ⊙ **Exercise 2.44** Write out, in formal notation, the probability a randomly selected person who was not inoculated died from smallpox, and find this probability.<sup>30</sup>

<sup>26</sup>(a)  $P(\text{parent} = \text{not} | \text{student} = \text{not})$ . (b) Equation (2.40) for conditional probability indicates we should first find  $P(\text{parents} = \text{not and student} = \text{not}) = 0.32$  and  $P(\text{student} = \text{not}) = 0.51$ . Then the ratio represents the conditional probability:  $0.32/0.51 = 0.63$ .

<sup>27</sup>(a) This probability is  $\frac{P(\text{parents} = \text{used and student} = \text{not})}{P(\text{student} = \text{not})} = \frac{0.19}{0.51} = 0.37$ . (b) The total equals 1. (c) Under the condition the student does not use drugs, the parents must either use drugs or not. The complement still appears to work *when conditioning on the same information*.

<sup>28</sup>No. This was an observational study. Two potential confounding variables include `income` and `region`. Can you think of others?

<sup>29</sup>Fenner F. 1988. *Smallpox and Its Eradication (History of International Public Health, No. 6)*. Geneva: World Health Organization. ISBN 92-4-156110-6.

<sup>30</sup> $P(\text{result} = \text{died} | \text{inoculated} = \text{no}) = \frac{P(\text{result} = \text{died and inoculated} = \text{no})}{P(\text{inoculated} = \text{no})} = \frac{0.1356}{0.9608} = 0.1411$ .

		inoculated		Total
		yes	no	
result	lived	238	5136	5374
	died	6	844	850
	Total	244	5980	6224

Table 2.15: Contingency table for the `smallpox` data set.

		inoculated		Total
		yes	no	
result	lived	0.0382	0.8252	0.8634
	died	0.0010	0.1356	0.1366
	Total	0.0392	0.9608	1.0000

Table 2.16: Table proportions for the `smallpox` data, computed by dividing each count by the table total, 6224.

- ⊙ **Exercise 2.45** Determine the probability that an inoculated person died from smallpox. How does this result compare with the result of Exercise 2.44?<sup>31</sup>
- ⊙ **Exercise 2.46** The people of Boston self-selected whether or not to be inoculated. (a) Is this study observational or was this an experiment? (b) Can we infer any causal connection using these data? (c) What are some potential confounding variables that might influence whether someone `lived` or `died` and also affect whether that person was inoculated?<sup>32</sup>

### 2.2.4 General multiplication rule

Section 2.1.6 introduced the Multiplication Rule for independent processes. Here we provide the **General Multiplication Rule** for events that might not be independent.

#### General Multiplication Rule

If  $A$  and  $B$  represent two outcomes or events, then

$$P(A \text{ and } B) = P(A|B) \times P(B)$$

It is useful to think of  $A$  as the outcome of interest and  $B$  as the condition.

This General Multiplication Rule is simply a rearrangement of the definition for conditional probability in Equation (2.40) on page 83.

<sup>31</sup> $P(\text{result} = \text{died} \mid \text{inoculated} = \text{yes}) = \frac{P(\text{result} = \text{died and inoculated} = \text{yes})}{P(\text{inoculated} = \text{yes})} = \frac{0.0010}{0.0392} = 0.0255$ . The death rate for individuals who were inoculated is only about 1 in 40 while the death rate is about 1 in 7 for those who were not inoculated.

<sup>32</sup>Brief answers: (a) Observational. (b) No, we cannot infer causation from this observational study. (c) Accessibility to the latest and best medical care. There are other valid answers for part (c).

- **Example 2.47** Consider the `smallpox` data set. Suppose we are given only two pieces of information: 96.08% of residents were not inoculated, and 85.88% of the residents who were not inoculated ended up surviving. How could we compute the probability that a resident was not inoculated and lived?

We will compute our answer using the General Multiplication Rule and then verify it using Table 2.16. We want to determine

$$P(\text{result} = \text{lived and inoculated} = \text{no})$$

and we are given that

$$P(\text{result} = \text{lived} \mid \text{inoculated} = \text{no}) = 0.8588$$

$$P(\text{inoculated} = \text{no}) = 0.9608$$

Among the 96.08% of people who were not inoculated, 85.88% survived:

$$P(\text{result} = \text{lived and inoculated} = \text{no}) = 0.8588 \times 0.9608 = 0.8251$$

This is equivalent to the General Multiplication Rule. We can confirm this probability in Table 2.16 at the intersection of `no` and `lived` (with a small rounding error).

- ⊙ **Exercise 2.48** Use  $P(\text{inoculated} = \text{yes}) = 0.0392$  and  $P(\text{result} = \text{lived} \mid \text{inoculated} = \text{yes}) = 0.9754$  to determine the probability that a person was both inoculated and lived.<sup>33</sup>
- ⊙ **Exercise 2.49** If 97.45% of the people who were inoculated lived, what proportion of inoculated people must have died?<sup>34</sup>

#### Sum of conditional probabilities

Let  $A_1, \dots, A_k$  represent all the disjoint outcomes for a variable or process. Then if  $B$  is an event, possibly for another variable or process, we have:

$$P(A_1|B) + \dots + P(A_k|B) = 1$$

The rule for complements also holds when an event and its complement are conditioned on the same information:

$$P(A|B) = 1 - P(A^c|B)$$

- ⊙ **Exercise 2.50** Based on the probabilities computed above, does it appear that inoculation is effective at reducing the risk of death from smallpox?<sup>35</sup>

<sup>33</sup>The answer is 0.0382, which can be verified using Table 2.16.

<sup>34</sup>There were only two possible outcomes: `lived` or `died`. This means that  $100\% - 97.45\% = 2.55\%$  of the people who were inoculated died.

<sup>35</sup>The samples are large relative to the difference in death rates for the “inoculated” and “not inoculated” groups, so it seems there is an association between `inoculated` and `outcome`. However, as noted in the solution to Exercise 2.46, this is an observational study and we cannot be sure if there is a causal connection. (Further research has shown that inoculation is effective at reducing death rates.)

### 2.2.5 Independence considerations in conditional probability

If two processes are independent, then knowing the outcome of one should provide no information about the other. We can show this is mathematically true using conditional probabilities.

- ⊙ **Exercise 2.51** Let  $X$  and  $Y$  represent the outcomes of rolling two dice. (a) What is the probability that the first die,  $X$ , is 1? (b) What is the probability that both  $X$  and  $Y$  are 1? (c) Use the formula for conditional probability to compute  $P(Y = 1 | X = 1)$ . (d) What is  $P(Y = 1)$ ? Is this different from the answer from part (c)? Explain.<sup>36</sup>

We can show in Exercise 2.51(c) that the conditioning information has no influence by using the Multiplication Rule for independence processes:

$$\begin{aligned} P(Y = 1 | X = 1) &= \frac{P(Y = 1 \text{ and } X = 1)}{P(X = 1)} \\ &= \frac{P(Y = 1) \times P(X = 1)}{P(X = 1)} \\ &= P(Y = 1) \end{aligned}$$

- ⊙ **Exercise 2.52** Ron is watching a roulette table in a casino and notices that the last five outcomes were **black**. He figures that the chances of getting **black** six times in a row is very small (about  $1/64$ ) and puts his paycheck on red. What is wrong with his reasoning?<sup>37</sup>

### 2.2.6 Tree diagrams

**Tree diagrams** are a tool to organize outcomes and probabilities around the structure of the data. They are most useful when two or more processes occur in a sequence and each process is conditioned on its predecessors.

The **smallpox** data fit this description. We see the population as split by **inoculation**: **yes** and **no**. Following this split, survival rates were observed for each group. This structure is reflected in the **tree diagram** shown in Figure 2.17. The first branch for **inoculation** is said to be the **primary** branch while the other branches are **secondary**.

Tree diagrams are annotated with marginal and conditional probabilities, as shown in Figure 2.17. This tree diagram splits the smallpox data by **inoculation** into the **yes** and **no** groups with respective marginal probabilities 0.0392 and 0.9608. The secondary branches are conditioned on the first, so we assign conditional probabilities to these branches. For example, the top branch in Figure 2.17 is the probability that **result** = **lived** conditioned on the information that **inoculated** = **yes**. We may (and usually do) construct joint probabilities at the end of each branch in our tree by multiplying the numbers we come

<sup>36</sup>Brief solutions: (a)  $1/6$ . (b)  $1/36$ . (c)  $\frac{P(Y = 1 \text{ and } X = 1)}{P(X = 1)} = \frac{1/36}{1/6} = 1/6$ . (d) The probability is the same as in part (c):  $P(Y = 1) = 1/6$ . The probability that  $Y = 1$  was unchanged by knowledge about  $X$ , which makes sense as  $X$  and  $Y$  are independent.

<sup>37</sup>He has forgotten that the next roulette spin is independent of the previous spins. Casinos do employ this practice; they post the last several outcomes of many betting games to trick unsuspecting gamblers into believing the odds are in their favor. This is called the **gambler's fallacy**.

Figure 2.17: A tree diagram of the `smallpox` data set.

across as we move from left to right. These joint probabilities are computed using the General Multiplication Rule:

$$\begin{aligned}
 P(\text{inoculated} = \text{yes and result} = \text{lived}) \\
 &= P(\text{inoculated} = \text{yes}) \times P(\text{result} = \text{lived} | \text{inoculated} = \text{yes}) \\
 &= 0.0392 \times 0.9754 = 0.0382
 \end{aligned}$$

- **Example 2.53** Consider the midterm and final for a statistics class. Suppose 13% of students earned an A on the midterm. Of those students who earned an A on the midterm, 47% received an A on the final, and 11% of the students who earned lower than an A on the midterm received an A on the final. You randomly pick up a final exam and notice the student received an A. What is the probability that this student earned an A on the midterm?

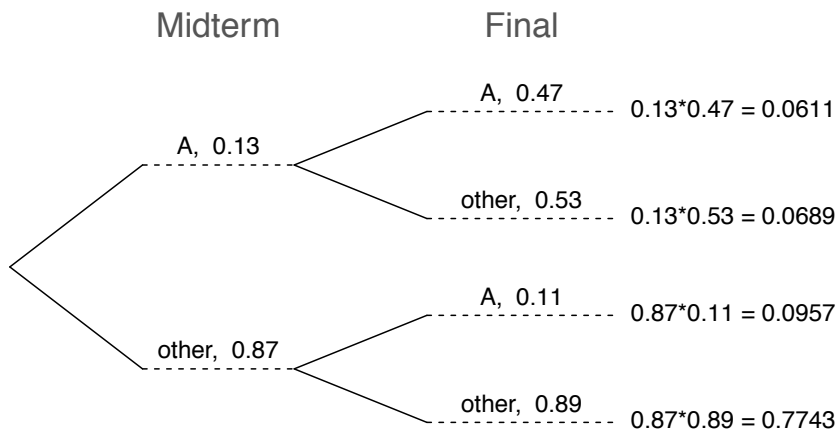

The end-goal is to find  $P(\text{midterm} = \text{A} | \text{final} = \text{A})$ . To calculate this conditional probability, we need the following probabilities:

$$P(\text{midterm} = \text{A and final} = \text{A}) \quad \text{and} \quad P(\text{final} = \text{A})$$

However, this information is not provided, and it is not obvious how to calculate these probabilities. Since we aren't sure how to proceed, it is useful to organize the information into a tree diagram, as shown in Figure 2.18. When constructing a tree diagram, variables provided with marginal probabilities are often used to create the tree's primary branches; in this case, the marginal probabilities are provided for midterm grades. The final grades, which correspond to the conditional probabilities provided, will be shown on the secondary branches.

With the tree diagram constructed, we may compute the required probabilities:

$$\begin{aligned}
 P(\text{midterm} = \text{A and final} = \text{A}) &= 0.0611 \\
 P(\text{final} = \text{A}) \\
 &= P(\text{midterm} = \text{other and final} = \text{A}) + P(\text{midterm} = \text{A and final} = \text{A}) \\
 &= 0.0611 + 0.0957 = 0.1568
 \end{aligned}$$

Figure 2.18: A tree diagram describing the `midterm` and `final` variables.

The marginal probability,  $P(\text{final} = A)$ , was calculated by adding up all the joint probabilities on the right side of the tree that correspond to `final` = A. We may now finally take the ratio of the two probabilities:

$$\begin{aligned}
 P(\text{midterm} = A | \text{final} = A) &= \frac{P(\text{midterm} = A \text{ and } \text{final} = A)}{P(\text{final} = A)} \\
 &= \frac{0.0611}{0.1568} = 0.3897
 \end{aligned}$$

The probability the student also earned an A on the midterm is about 0.39.

- ⊙ **Exercise 2.54** After an introductory statistics course, 78% of students can successfully construct tree diagrams. Of those who can construct tree diagrams, 97% passed, while only 57% of those students who could not construct tree diagrams passed. (a) Organize this information into a tree diagram. (b) What is the probability that a randomly selected student passed? (c) Compute the probability a student is able to construct a tree diagram if it is known that she passed.<sup>38</sup>

<sup>38</sup>(a) The tree diagram is shown to the right. (b) Identify which two joint probabilities represent students who passed, and add them:  $P(\text{passed}) = 0.7566 + 0.1254 = 0.8820$ . (c)  $P(\text{construct tree diagram} | \text{passed}) = \frac{0.7566}{0.8820} = 0.8578$ .

### 2.2.7 Bayes' Theorem

In many instances, we are given a conditional probability of the form

$$P(\text{statement about variable 1} \mid \text{statement about variable 2})$$

but we would really like to know the inverted conditional probability:

$$P(\text{statement about variable 2} \mid \text{statement about variable 1})$$

Tree diagrams can be used to find the second conditional probability when given the first. However, sometimes it is not possible to draw the scenario in a tree diagram. In these cases, we can apply a very useful and general formula: Bayes' Theorem.

We first take a critical look at an example of inverting conditional probabilities where we still apply a tree diagram.

- **Example 2.55** In Canada, about 0.35% of women over 40 will be diagnosed with breast cancer in any given year. A common screening test for cancer is the mammogram, but this test is not perfect. In about 11% of patients with breast cancer, the test gives a **false negative**: it indicates a woman does not have breast cancer when she does have breast cancer. Similarly, the test gives a **false positive** in 7% of patients who do not have breast cancer: it indicates these patients have breast cancer when they actually do not.<sup>39</sup> If we tested a random woman over 40 for breast cancer using a mammogram and the test came back positive – that is, the test suggested the patient has cancer – what is the probability that the patient actually has breast cancer?

Figure 2.19: Tree diagram for Example 2.55, computing the probability a random patient who tests positive on a mammogram actually has breast cancer.

Notice that we are given sufficient information to quickly compute the probability of testing positive if a woman has breast cancer ( $1.00 - 0.11 = 0.89$ ). However, we seek the inverted probability of cancer given a positive test result. (Watch out for the non-intuitive medical language: a *positive* test result suggests the possible presence

<sup>39</sup>The probabilities reported here were obtained using studies reported at [www.breastcancer.org](http://www.breastcancer.org) and [www.ncbi.nlm.nih.gov/pmc/articles/PMC1173421](http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1173421).

of cancer in a mammogram screening.) This inverted probability may be broken into two pieces:

$$P(\text{has BC} \mid \text{mammogram}^+) = \frac{P(\text{has BC and mammogram}^+)}{P(\text{mammogram}^+)}$$

where “has BC” is an abbreviation for the patient actually having breast cancer and “mammogram<sup>+</sup>” means the mammogram screening was positive. A tree diagram is useful for identifying each probability and is shown in Figure 2.19. The probability the patient has breast cancer and the mammogram is positive is

$$\begin{aligned} P(\text{has BC and mammogram}^+) &= P(\text{mammogram}^+ \mid \text{has BC})P(\text{has BC}) \\ &= 0.89 \times 0.0035 = 0.00312 \end{aligned}$$

The probability of a positive test result is the sum of the two corresponding scenarios:

$$\begin{aligned} P(\text{mammogram}^+) &= P(\text{mammogram}^+ \text{ and has BC}) + P(\text{mammogram}^+ \text{ and no BC}) \\ &= P(\text{has BC})P(\text{mammogram}^+ \mid \text{has BC}) \\ &\quad + P(\text{no BC})P(\text{mammogram}^+ \mid \text{no BC}) \\ &= 0.0035 \times 0.89 + 0.9965 \times 0.07 = 0.07288 \end{aligned}$$

Then if the mammogram screening is positive for a patient, the probability the patient has breast cancer is

$$\begin{aligned} P(\text{has BC} \mid \text{mammogram}^+) &= \frac{P(\text{has BC and mammogram}^+)}{P(\text{mammogram}^+)} \\ &= \frac{0.00312}{0.07288} \approx 0.0428 \end{aligned}$$

That is, even if a patient has a positive mammogram screening, there is still only a 4% chance that she has breast cancer.

Example 2.55 highlights why doctors often run more tests regardless of a first positive test result. When a medical condition is rare, a single positive test isn’t generally definitive.

Consider again the last equation of Example 2.55. Using the tree diagram, we can see that the numerator (the top of the fraction) is equal to the following product:

$$P(\text{has BC and mammogram}^+) = P(\text{mammogram}^+ \mid \text{has BC})P(\text{has BC})$$

The denominator – the probability the screening was positive – is equal to the sum of probabilities for each positive screening scenario:

$$P(\text{mammogram}^+) = P(\text{mammogram}^+ \text{ and no BC}) + P(\text{mammogram}^+ \text{ and has BC})$$

In the example, each of the probabilities on the right side was broken down into a product of a conditional probability and marginal probability using the tree diagram.

$$\begin{aligned} P(\text{mammogram}^+) &= P(\text{mammogram}^+ \text{ and no BC}) + P(\text{mammogram}^+ \text{ and has BC}) \\ &= P(\text{mammogram}^+ \mid \text{no BC})P(\text{no BC}) \\ &\quad + P(\text{mammogram}^+ \mid \text{has BC})P(\text{has BC}) \end{aligned}$$

We can see an application of Bayes' Theorem by substituting the resulting probability expressions into the numerator and denominator of the original conditional probability.

$$\begin{aligned}
 &P(\text{has BC} \mid \text{mammogram}^+) \\
 &= \frac{P(\text{mammogram}^+ \mid \text{has BC})P(\text{has BC})}{P(\text{mammogram}^+ \mid \text{no BC})P(\text{no BC}) + P(\text{mammogram}^+ \mid \text{has BC})P(\text{has BC})}
 \end{aligned}$$

### Bayes' Theorem: inverting probabilities

Consider the following conditional probability for variable 1 and variable 2:

$$P(\text{outcome } A_1 \text{ of variable 1} \mid \text{outcome } B \text{ of variable 2})$$

Bayes' Theorem states that this conditional probability can be identified as the following fraction:

$$\frac{P(B|A_1)P(A_1)}{P(B|A_1)P(A_1) + P(B|A_2)P(A_2) + \cdots + P(B|A_k)P(A_k)} \quad (2.56)$$

where  $A_2, A_3, \dots$ , and  $A_k$  represent all other possible outcomes of the first variable.

Bayes' Theorem is just a generalization of what we have done using tree diagrams. The numerator identifies the probability of getting both  $A_1$  and  $B$ . The denominator is the marginal probability of getting  $B$ . This bottom component of the fraction appears long and complicated since we have to add up probabilities from all of the different ways to get  $B$ . We always completed this step when using tree diagrams. However, we usually did it in a separate step so it didn't seem as complex.

To apply Bayes' Theorem correctly, there are two preparatory steps:

- (1) First identify the marginal probabilities of each possible outcome of the first variable:  $P(A_1), P(A_2), \dots, P(A_k)$ .
- (2) Then identify the probability of the outcome  $B$ , conditioned on each possible scenario for the first variable:  $P(B|A_1), P(B|A_2), \dots, P(B|A_k)$ .

Once each of these probabilities are identified, they can be applied directly within the formula.

### TIP: Only use Bayes' Theorem when tree diagrams are difficult

Drawing a tree diagram makes it easier to understand how two variables are connected. Use Bayes' Theorem only when there are so many scenarios that drawing a tree diagram would be complex.

- ⊙ **Exercise 2.57** Jose visits campus every Thursday evening. However, some days the parking garage is full, often due to college events. There are academic events on 35% of evenings, sporting events on 20% of evenings, and no events on 45% of evenings. When there is an academic event, the garage fills up about 25% of the time, and it fills up 70% of evenings with sporting events. On evenings when there are no events, it only fills up about 5% of the time. If Jose comes to campus and finds the garage full, what is the probability that there is a sporting event? Use a tree diagram to solve this problem.<sup>40</sup>

- **Example 2.58** Here we solve the same problem presented in Exercise 2.57, except this time we use Bayes' Theorem.

The outcome of interest is whether there is a sporting event (call this  $A_1$ ), and the condition is that the lot is full ( $B$ ). Let  $A_2$  represent an academic event and  $A_3$  represent there being no event on campus. Then the given probabilities can be written as

$$\begin{array}{lll} P(A_1) = 0.2 & P(A_2) = 0.35 & P(A_3) = 0.45 \\ P(B|A_1) = 0.7 & P(B|A_2) = 0.25 & P(B|A_3) = 0.05 \end{array}$$

Bayes' Theorem can be used to compute the probability of a sporting event ( $A_1$ ) under the condition that the parking lot is full ( $B$ ):

$$\begin{aligned} P(A_1|B) &= \frac{P(B|A_1)P(A_1)}{P(B|A_1)P(A_1) + P(B|A_2)P(A_2) + P(B|A_3)P(A_3)} \\ &= \frac{(0.7)(0.2)}{(0.7)(0.2) + (0.25)(0.35) + (0.05)(0.45)} \\ &= 0.56 \end{aligned}$$

Based on the information that the garage is full, there is a 56% probability that a sporting event is being held on campus that evening.

- ⊙ **Exercise 2.59** Use the information in the previous exercise and example to verify the probability that there is an academic event conditioned on the parking lot being full is 0.35.<sup>41</sup>

<sup>40</sup>The tree diagram, with three primary branches, is shown to the right. Next, we identify two probabilities from the tree diagram. (1) The probability that there is a sporting event and the garage is full:  $0.0875 + 0.14 + 0.0225 = 0.25$ . Then the solution is the ratio of these probabilities:  $\frac{0.14}{0.25} = 0.56$ . If the garage is full, there is a 56% probability that there is a sporting event.

<sup>41</sup>Short answer:

$$\begin{aligned} P(A_2|B) &= \frac{P(B|A_2)P(A_2)}{P(B|A_1)P(A_1) + P(B|A_2)P(A_2) + P(B|A_3)P(A_3)} \\ &= \frac{(0.25)(0.35)}{(0.7)(0.2) + (0.25)(0.35) + (0.05)(0.45)} \\ &= 0.35 \end{aligned}$$

- ⊙ **Exercise 2.60** In Exercise 2.57 and 2.59, you found that if the parking lot is full, the probability a sporting event is 0.56 and the probability there is an academic event is 0.35. Using this information, compute  $P(\text{no event} \mid \text{the lot is full})$ .<sup>42</sup>

The last several exercises offered a way to update our belief about whether there is a sporting event, academic event, or no event going on at the school based on the information that the parking lot was full. This strategy of *updating beliefs* using Bayes' Theorem is actually the foundation of an entire section of statistics called **Bayesian statistics**. While Bayesian statistics is very important and useful, we will not have time to cover much more of it in this book.

## 2.3 Sampling from a small population (special topic)

- **Example 2.61** Professors sometimes select a student at random to answer a question. If each student has an equal chance of being selected and there are 15 people in your class, what is the chance that she will pick you for the next question?

If there are 15 people to ask and none are skipping class, then the probability is  $1/15$ , or about 0.067.

- **Example 2.62** If the professor asks 3 questions, what is the probability that you will not be selected? Assume that she will not pick the same person twice in a given lecture.

For the first question, she will pick someone else with probability  $14/15$ . When she asks the second question, she only has 14 people who have not yet been asked. Thus, if you were not picked on the first question, the probability you are again not picked is  $13/14$ . Similarly, the probability you are again not picked on the third question is  $12/13$ , and the probability of not being picked for any of the three questions is

$$\begin{aligned} &P(\text{not picked in 3 questions}) \\ &= P(Q1 = \text{not\_picked}, Q2 = \text{not\_picked}, Q3 = \text{not\_picked.}) \\ &= \frac{14}{15} \times \frac{13}{14} \times \frac{12}{13} = \frac{12}{15} = 0.80 \end{aligned}$$

- ⊙ **Exercise 2.63** What rule permitted us to multiply the probabilities in Example 2.62?<sup>43</sup>

<sup>42</sup>Each probability is conditioned on the same information that the garage is full, so the complement may be used:  $1.00 - 0.56 - 0.35 = 0.09$ .

<sup>43</sup>The three probabilities we computed were actually one marginal probability,  $P(Q1=\text{not\_picked})$ , and two conditional probabilities:

$$\begin{aligned} &P(Q2 = \text{not\_picked} \mid Q1 = \text{not\_picked}) \\ &P(Q3 = \text{not\_picked} \mid Q1 = \text{not\_picked}, Q2 = \text{not\_picked}) \end{aligned}$$

Using the General Multiplication Rule, the product of these three probabilities is the probability of not being picked in 3 questions.

- **Example 2.64** Suppose the professor randomly picks without regard to who she already selected, i.e. students can be picked more than once. What is the probability that you will not be picked for any of the three questions?

Each pick is independent, and the probability of not being picked for any individual question is  $14/15$ . Thus, we can use the Multiplication Rule for independent processes.

$$\begin{aligned} P(\text{not picked in 3 questions}) \\ &= P(Q1 = \text{not\_picked}, Q2 = \text{not\_picked}, Q3 = \text{not\_picked.}) \\ &= \frac{14}{15} \times \frac{14}{15} \times \frac{14}{15} = 0.813 \end{aligned}$$

You have a slightly higher chance of not being picked compared to when she picked a new person for each question. However, you now may be picked more than once.

- ⊙ **Exercise 2.65** Under the setup of Example 2.64, what is the probability of being picked to answer all three questions?<sup>44</sup>

If we sample from a small population **without replacement**, we no longer have independence between our observations. In Example 2.62, the probability of not being picked for the second question was conditioned on the event that you were not picked for the first question. In Example 2.64, the professor sampled her students **with replacement**: she repeatedly sampled the entire class without regard to who she already picked.

- ⊙ **Exercise 2.66** Your department is holding a raffle. They sell 30 tickets and offer seven prizes. (a) They place the tickets in a hat and draw one for each prize. The tickets are sampled without replacement, i.e. the selected tickets are not placed back in the hat. What is the probability of winning a prize if you buy one ticket? (b) What if the tickets are sampled with replacement?<sup>45</sup>
- ⊙ **Exercise 2.67** Compare your answers in Exercise 2.66. How much influence does the sampling method have on your chances of winning a prize?<sup>46</sup>

Had we repeated Exercise 2.66 with 300 tickets instead of 30, we would have found something interesting: the results would be nearly identical. The probability would be 0.0233 without replacement and 0.0231 with replacement. When the sample size is only a small fraction of the population (under 10%), observations are nearly independent even when sampling without replacement.

<sup>44</sup> $P(\text{being picked to answer all three questions}) = \left(\frac{1}{15}\right)^3 = 0.00030$ .

<sup>45</sup>(a) First determine the probability of not winning. The tickets are sampled without replacement, which means the probability you do not win on the first draw is  $29/30$ ,  $28/29$  for the second, ..., and  $23/24$  for the seventh. The probability you win no prize is the product of these separate probabilities:  $23/30$ . That is, the probability of winning a prize is  $1 - 23/30 = 7/30 = 0.233$ . (b) When the tickets are sampled with replacement, there are seven independent draws. Again we first find the probability of not winning a prize:  $(29/30)^7 = 0.789$ . Thus, the probability of winning (at least) one prize when drawing with replacement is 0.211.

<sup>46</sup>There is about a 10% larger chance of winning a prize when using sampling without replacement. However, at most one prize may be won under this sampling procedure.

## 2.4 Random variables (special topic)

- **Example 2.68** Two books are assigned for a statistics class: a textbook and its corresponding study guide. The university bookstore determined 20% of enrolled students do not buy either book, 55% buy the textbook only, and 25% buy both books, and these percentages are relatively constant from one term to another. If there are 100 students enrolled, how many books should the bookstore expect to sell to this class?

Around 20 students will not buy either book (0 books total), about 55 will buy one book (55 books total), and approximately 25 will buy two books (totaling 50 books for these 25 students). The bookstore should expect to sell about 105 books for this class.

- **Exercise 2.69** Would you be surprised if the bookstore sold slightly more or less than 105 books?<sup>47</sup>

- **Example 2.70** The textbook costs \$137 and the study guide \$33. How much revenue should the bookstore expect from this class of 100 students?

About 55 students will just buy a textbook, providing revenue of

$$\$137 \times 55 = \$7,535$$

The roughly 25 students who buy both the textbook and the study guide would pay a total of

$$(\$137 + \$33) \times 25 = \$170 \times 25 = \$4,250$$

Thus, the bookstore should expect to generate about  $\$7,535 + \$4,250 = \$11,785$  from these 100 students for this one class. However, there might be some *sampling variability* so the actual amount may differ by a little bit.

- **Example 2.71** What is the average revenue per student for this course?

The expected total revenue is \$11,785, and there are 100 students. Therefore the expected revenue per student is  $\$11,785/100 = \$117.85$ .

### 2.4.1 Expectation

We call a variable or process with a numerical outcome a **random variable**, and we usually represent this random variable with a capital letter such as  $X$ ,  $Y$ , or  $Z$ . The amount of money a single student will spend on her statistics books is a random variable, and we represent it by  $X$ .

#### Random variable

A random process or variable with a numerical outcome.

<sup>47</sup>If they sell a little more or a little less, this should not be a surprise. Hopefully Chapter 1 helped make clear that there is natural variability in observed data. For example, if we would flip a coin 100 times, it will not usually come up heads exactly half the time, but it will probably be close.

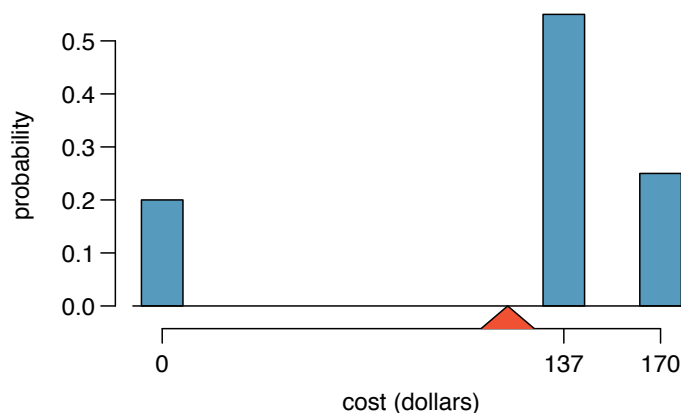

Figure 2.20: Probability distribution for the bookstore's revenue from a single student. The distribution balances on a triangle representing the average revenue per student.

$i$	1	2	3	Total
$x_i$	\$0	\$137	\$170	–
$P(X = x_i)$	0.20	0.55	0.25	1.00

Table 2.21: The probability distribution for the random variable  $X$ , representing the bookstore's revenue from a single student.

The possible outcomes of  $X$  are labeled with a corresponding lower case letter  $x$  and subscripts. For example, we write  $x_1 = \$0$ ,  $x_2 = \$137$ , and  $x_3 = \$170$ , which occur with probabilities 0.20, 0.55, and 0.25. The distribution of  $X$  is summarized in Figure 2.20 and Table 2.21.

We computed the average outcome of  $X$  as \$117.85 in Example 2.71. We call this average the **expected value** of  $X$ , denoted by  $E(X)$ . The expected value of a random variable is computed by adding each outcome weighted by its probability:

$$\begin{aligned} E(X) &= 0 \times P(X = 0) + 137 \times P(X = 137) + 170 \times P(X = 170) \\ &= 0 \times 0.20 + 137 \times 0.55 + 170 \times 0.25 = 117.85 \end{aligned}$$

$E(X)$   
Expected  
value of  $X$

#### Expected value of a Discrete Random Variable

If  $X$  takes outcomes  $x_1, \dots, x_k$  with probabilities  $P(X = x_1), \dots, P(X = x_k)$ , the expected value of  $X$  is the sum of each outcome multiplied by its corresponding probability:

$$\begin{aligned} E(X) &= x_1 \times P(X = x_1) + \dots + x_k \times P(X = x_k) \\ &= \sum_{i=1}^k x_i P(X = x_i) \end{aligned} \tag{2.72}$$

The Greek letter  $\mu$  may be used in place of the notation  $E(X)$ .

Figure 2.22: A weight system representing the probability distribution for  $X$ . The string holds the distribution at the mean to keep the system balanced.

Figure 2.23: A continuous distribution can also be balanced at its mean.

The expected value for a random variable represents the average outcome. For example,  $E(X) = 117.85$  represents the average amount the bookstore expects to make from a single student, which we could also write as  $\mu = 117.85$ .

It is also possible to compute the expected value of a continuous random variable (see Section 2.5). However, it requires a little calculus and we save it for a later class.<sup>48</sup>

In physics, the expectation holds the same meaning as the center of gravity. The distribution can be represented by a series of weights at each outcome, and the mean represents the balancing point. This is represented in Figures 2.20 and 2.22. The idea of a center of gravity also expands to continuous probability distributions. Figure 2.23 shows a continuous probability distribution balanced atop a wedge placed at the mean.

<sup>48</sup> $\mu = \int xf(x)dx$  where  $f(x)$  represents a function for the density curve.

### 2.4.2 Variability in random variables

Suppose you ran the university bookstore. Besides how much revenue you expect to generate, you might also want to know the volatility (variability) in your revenue.

The variance and standard deviation can be used to describe the variability of a random variable. Section 1.6.4 introduced a method for finding the variance and standard deviation for a data set. We first computed deviations from the mean ( $x_i - \mu$ ), squared those deviations, and took an average to get the variance. In the case of a random variable, we again compute squared deviations. However, we take their sum weighted by their corresponding probabilities, just like we did for the expectation. This weighted sum of squared deviations equals the variance, and we calculate the standard deviation by taking the square root of the variance, just as we did in Section 1.6.4.

$Var(X)$   
Variance  
of  $X$

#### General variance formula

If  $X$  takes outcomes  $x_1, \dots, x_k$  with probabilities  $P(X = x_1), \dots, P(X = x_k)$  and expected value  $\mu = E(X)$ , then the variance of  $X$ , denoted by  $Var(X)$  or the symbol  $\sigma^2$ , is

$$\begin{aligned}\sigma^2 &= (x_1 - \mu)^2 \times P(X = x_1) + \dots \\ &\quad \dots + (x_k - \mu)^2 \times P(X = x_k) \\ &= \sum_{j=1}^k (x_j - \mu)^2 P(X = x_j)\end{aligned}\tag{2.73}$$

The standard deviation of  $X$ , labeled  $\sigma$ , is the square root of the variance.

● **Example 2.74** Compute the expected value, variance, and standard deviation of  $X$ , the revenue of a single statistics student for the bookstore.

It is useful to construct a table that holds computations for each outcome separately, then add up the results.

$i$	1	2	3	Total
$x_i$	\$0	\$137	\$170	
$P(X = x_i)$	0.20	0.55	0.25	
$x_i \times P(X = x_i)$	0	75.35	42.50	117.85

Thus, the expected value is  $\mu = 117.85$ , which we computed earlier. The variance can be constructed by extending this table:

$i$	1	2	3	Total
$x_i$	\$0	\$137	\$170	
$P(X = x_i)$	0.20	0.55	0.25	
$x_i \times P(X = x_i)$	0	75.35	42.50	117.85
$x_i - \mu$	-117.85	19.15	52.15	
$(x_i - \mu)^2$	13888.62	366.72	2719.62	
$(x_i - \mu)^2 \times P(X = x_i)$	2777.7	201.7	679.9	3659.3

The variance of  $X$  is  $\sigma^2 = 3659.3$ , which means the standard deviation is  $\sigma = \sqrt{3659.3} = \$60.49$ .

⊙ **Exercise 2.75** The bookstore also offers a chemistry textbook for \$159 and a book supplement for \$41. From past experience, they know about 25% of chemistry students just buy the textbook while 60% buy both the textbook and supplement.<sup>49</sup>

- What proportion of students don't buy either book? Assume no students buy the supplement without the textbook.
- Let  $Y$  represent the revenue from a single student. Write out the probability distribution of  $Y$ , i.e. a table for each outcome and its associated probability.
- Compute the expected revenue from a single chemistry student.
- Find the standard deviation to describe the variability associated with the revenue from a single student.

### 2.4.3 Linear combinations of random variables

So far, we have thought of each variable as being a complete story in and of itself. Sometimes it is more appropriate to use a combination of variables. For instance, the amount of time a person spends commuting to work each week can be broken down into several daily commutes. Similarly, the total gain or loss in a stock portfolio is the sum of the gains and losses in its components.

● **Example 2.76** John travels to work five days a week. We will use  $X_1$  to represent his travel time on Monday,  $X_2$  to represent his travel time on Tuesday, and so on. Write an equation using  $X_1, \dots, X_5$  that represents his travel time for the week, denoted by  $W$ .

His total weekly travel time is the sum of the five daily values:

$$W = X_1 + X_2 + X_3 + X_4 + X_5$$

Breaking the weekly travel time  $W$  into pieces provides a framework for understanding each source of randomness and is useful for modeling  $W$ .

● **Example 2.77** It takes John an average of 18 minutes each day to commute to work. What would you expect his average commute time to be for the week?

We were told that the average (i.e. expected value) of the commute time is 18 minutes per day:  $E(X_i) = 18$ . To get the expected time for the sum of the five days, we can add up the expected time for each individual day:

$$\begin{aligned} E(W) &= E(X_1 + X_2 + X_3 + X_4 + X_5) \\ &= E(X_1) + E(X_2) + E(X_3) + E(X_4) + E(X_5) \\ &= 18 + 18 + 18 + 18 + 18 = 90 \text{ minutes} \end{aligned}$$

<sup>49</sup>(a)  $100\% - 25\% - 60\% = 15\%$  of students do not buy any books for the class. Part (b) is represented by the first two lines in the table below. The expectation for part (c) is given as the total on the line  $y_i \times P(Y = y_i)$ . The result of part (d) is the square-root of the variance listed on in the total on the last line:  $\sigma = \sqrt{\text{Var}(Y)} = \$69.28$ .

$i$ (scenario)	1 (noBook)	2 (textbook)	3 (both)	Total
$y_i$	0.00	159.00	200.00	
$P(Y = y_i)$	0.15	0.25	0.60	
$y_i \times P(Y = y_i)$	0.00	39.75	120.00	$E(Y) = 159.75$
$y_i - E(Y)$	-159.75	-0.75	40.25	
$(y_i - E(Y))^2$	25520.06	0.56	1620.06	
$(y_i - E(Y))^2 \times P(Y)$	3828.0	0.1	972.0	$\text{Var}(Y) \approx 4800$

The expectation of the total time is equal to the sum of the expected individual times. More generally, the expectation of a sum of random variables is always the sum of the expectation for each random variable.

- ⊙ **Exercise 2.78** Elena is selling a TV at a cash auction and also intends to buy a toaster oven in the auction. If  $X$  represents the profit for selling the TV and  $Y$  represents the cost of the toaster oven, write an equation that represents the net change in Elena's cash.<sup>50</sup>
- ⊙ **Exercise 2.79** Based on past auctions, Elena figures she should expect to make about \$175 on the TV and pay about \$23 for the toaster oven. In total, how much should she expect to make or spend?<sup>51</sup>
- ⊙ **Exercise 2.80** Would you be surprised if John's weekly commute wasn't exactly 90 minutes or if Elena didn't make exactly \$152? Explain.<sup>52</sup>

Two important concepts concerning combinations of random variables have so far been introduced. First, a final value can sometimes be described as the sum of its parts in an equation. Second, intuition suggests that putting the individual average values into this equation gives the average value we would expect in total. This second point needs clarification – it is guaranteed to be true in what are called *linear combinations of random variables*.

A **linear combination** of two random variables  $X$  and  $Y$  is a fancy phrase to describe a combination

$$aX + bY$$

where  $a$  and  $b$  are some fixed and known numbers. For John's commute time, there were five random variables – one for each work day – and each random variable could be written as having a fixed coefficient of 1:

$$1X_1 + 1X_2 + 1X_3 + 1X_4 + 1X_5$$

For Elena's net gain or loss, the  $X$  random variable had a coefficient of +1 and the  $Y$  random variable had a coefficient of -1.

When considering the average of a linear combination of random variables, it is safe to plug in the mean of each random variable and then compute the final result. For a few examples of nonlinear combinations of random variables – cases where we cannot simply plug in the means – see the footnote.<sup>53</sup>

<sup>50</sup>She will make  $X$  dollars on the TV but spend  $Y$  dollars on the toaster oven:  $X - Y$ .

<sup>51</sup> $E(X - Y) = E(X) - E(Y) = 175 - 23 = \$152$ . She should expect to make about \$152.

<sup>52</sup>No, since there is probably some variability. For example, the traffic will vary from one day to next, and auction prices will vary depending on the quality of the merchandise and the interest of the attendees.

<sup>53</sup>If  $X$  and  $Y$  are random variables, consider the following combinations:  $X^{1+Y}$ ,  $X \times Y$ ,  $X/Y$ . In such cases, plugging in the average value for each random variable and computing the result will not generally lead to an accurate average value for the end result.

**Linear combinations of random variables and the average result**

If  $X$  and  $Y$  are random variables, then a linear combination of the random variables is given by

$$aX + bY \quad (2.81)$$

where  $a$  and  $b$  are some fixed numbers. To compute the average value of a linear combination of random variables, plug in the average of each individual random variable and compute the result:

$$a \times E(X) + b \times E(Y)$$

Recall that the expected value is the same as the mean, e.g.  $E(X) = \mu_X$ .

- **Example 2.82** Leonard has invested \$6000 in Google Inc. (stock ticker: GOOG) and \$2000 in Exxon Mobil Corp. (XOM). If  $X$  represents the change in Google's stock next month and  $Y$  represents the change in Exxon Mobil stock next month, write an equation that describes how much money will be made or lost in Leonard's stocks for the month.

For simplicity, we will suppose  $X$  and  $Y$  are not in percents but are in decimal form (e.g. if Google's stock increases 1%, then  $X = 0.01$ ; or if it loses 1%, then  $X = -0.01$ ). Then we can write an equation for Leonard's gain as

$$\$6000 \times X + \$2000 \times Y$$

If we plug in the change in the stock value for  $X$  and  $Y$ , this equation gives the change in value of Leonard's stock portfolio for the month. A positive value represents a gain, and a negative value represents a loss.

- **Exercise 2.83** Suppose Google and Exxon Mobil stocks have recently been rising 2.1% and 0.4% per month, respectively. Compute the expected change in Leonard's stock portfolio for next month.<sup>54</sup>
- **Exercise 2.84** You should have found that Leonard expects a positive gain in Exercise 2.83. However, would you be surprised if he actually had a loss this month?<sup>55</sup>

#### 2.4.4 Variability in linear combinations of random variables

Quantifying the average outcome from a linear combination of random variables is helpful, but it is also important to have some sense of the uncertainty associated with the total outcome of that combination of random variables. The expected net gain or loss of Leonard's stock portfolio was considered in Exercise 2.83. However, there was no quantitative discussion of the volatility of this portfolio. For instance, while the average monthly gain might be about \$134 according to the data, that gain is not guaranteed. Figure 2.24 shows the monthly changes in a portfolio like Leonard's during the 36 months from 2009 to 2011. The gains and losses vary widely, and quantifying these fluctuations is important when investing in stocks.

<sup>54</sup>  $E(\$6000 \times X + \$2000 \times Y) = \$6000 \times 0.021 + \$2000 \times 0.004 = \$134$ .

<sup>55</sup> No. While stocks tend to rise over time, they are often volatile in the short term.

Figure 2.24: The change in a portfolio like Leonard’s for the 36 months from 2009 to 2011, where \$6000 is in Google’s stock and \$2000 is in Exxon Mobil’s.

	Mean ( $\bar{x}$ )	Standard deviation ( $s$ )	Variance ( $s^2$ )
GOOG	0.0210	0.0846	0.0072
XOM	0.0038	0.0519	0.0027

Table 2.25: The mean, standard deviation, and variance of the GOOG and XOM stocks. These statistics were estimated from historical stock data, so notation used for sample statistics has been used.

Just as we have done in many previous cases, we use the variance and standard deviation to describe the uncertainty associated with Leonard’s monthly returns. To do so, the variances of each stock’s monthly return will be useful, and these are shown in Table 2.25. The stocks’ returns are nearly independent.

Here we use an equation from probability theory to describe the uncertainty of Leonard’s monthly returns; we leave the proof of this method to a dedicated probability course. The variance of a linear combination of random variables can be computed by plugging in the variances of the individual random variables and squaring the coefficients of the random variables:

$$\text{Var}(aX + bY) = a^2 \times \text{Var}(X) + b^2 \times \text{Var}(Y)$$

It is important to note that this equality assumes the random variables are independent; if independence doesn’t hold, then more advanced methods are necessary. This equation can be used to compute the variance of Leonard’s monthly return:

$$\begin{aligned} \text{Var}(6000 \times X + 2000 \times Y) &= 6000^2 \times \text{Var}(X) + 2000^2 \times \text{Var}(Y) \\ &= 36,000,000 \times 0.0072 + 4,000,000 \times 0.0027 \\ &= 270,000 \end{aligned}$$

The standard deviation is computed as the square root of the variance:  $\sqrt{270,000} = \$520$ . While an average monthly return of \$134 on an \$8000 investment is nothing to scoff at, the monthly returns are so volatile that Leonard should not expect this income to be very stable.

**Variability of linear combinations of random variables**

The variance of a linear combination of random variables may be computed by squaring the constants, substituting in the variances for the random variables, and computing the result:

$$\text{Var}(aX + bY) = a^2 \times \text{Var}(X) + b^2 \times \text{Var}(Y)$$

This equation is valid as long as the random variables are independent of each other. The standard deviation of the linear combination may be found by taking the square root of the variance.

- **Example 2.85** Suppose John's daily commute has a standard deviation of 4 minutes. What is the uncertainty in his total commute time for the week?

The expression for John's commute time was

$$X_1 + X_2 + X_3 + X_4 + X_5$$

Each coefficient is 1, and the variance of each day's time is  $4^2 = 16$ . Thus, the variance of the total weekly commute time is

$$\text{variance} = 1^2 \times 16 + 1^2 \times 16 + 1^2 \times 16 + 1^2 \times 16 + 1^2 \times 16 = 5 \times 16 = 80$$

$$\text{standard deviation} = \sqrt{\text{variance}} = \sqrt{80} = 8.94$$

The standard deviation for John's weekly work commute time is about 9 minutes.

- ⊙ **Exercise 2.86** The computation in Example 2.85 relied on an important assumption: the commute time for each day is independent of the time on other days of that week. Do you think this is valid? Explain.<sup>56</sup>
- ⊙ **Exercise 2.87** Consider Elena's two auctions from Exercise 2.78 on page 100. Suppose these auctions are approximately independent and the variability in auction prices associated with the TV and toaster oven can be described using standard deviations of \$25 and \$8. Compute the standard deviation of Elena's net gain.<sup>57</sup>

Consider again Exercise 2.87. The negative coefficient for  $Y$  in the linear combination was eliminated when we squared the coefficients. This generally holds true: negatives in a linear combination will have no impact on the variability computed for a linear combination, but they do impact the expected value computations.

<sup>56</sup>One concern is whether traffic patterns tend to have a weekly cycle (e.g. Fridays may be worse than other days). If that is the case, and John drives, then the assumption is probably not reasonable. However, if John walks to work, then his commute is probably not affected by any weekly traffic cycle.

<sup>57</sup>The equation for Elena can be written as

$$(1) \times X + (-1) \times Y$$

The variances of  $X$  and  $Y$  are 625 and 64. We square the coefficients and plug in the variances:

$$(1)^2 \times \text{Var}(X) + (-1)^2 \times \text{Var}(Y) = 1 \times 625 + 1 \times 64 = 689$$

The variance of the linear combination is 689, and the standard deviation is the square root of 689: about \$26.25.

## 2.5 Continuous distributions (special topic)

- **Example 2.88** Figure 2.26 shows a few different hollow histograms of the variable **height** for 3 million US adults from the mid-90's.<sup>58</sup> How does changing the number of bins allow you to make different interpretations of the data?

Adding more bins provides greater detail. This sample is extremely large, which is why much smaller bins still work well. Usually we do not use so many bins with smaller sample sizes since small counts per bin mean the bin heights are very volatile.

Figure 2.26: Four hollow histograms of US adults heights with varying bin widths.

- **Example 2.89** What proportion of the sample is between 180 cm and 185 cm tall (about 5'11" to 6'1")?

We can add up the heights of the bins in the range 180 cm and 185 and divide by the sample size. For instance, this can be done with the two shaded bins shown in Figure 2.27. The two bins in this region have counts of 195,307 and 156,239 people, resulting in the following estimate of the probability:

$$\frac{195307 + 156239}{3,000,000} = 0.1172$$

This fraction is the same as the proportion of the histogram's area that falls in the range 180 to 185 cm.

<sup>58</sup>This sample can be considered a simple random sample from the US population. It relies on the USDA Food Commodity Intake Database.

Figure 2.27: A histogram with bin sizes of 2.5 cm. The shaded region represents individuals with heights between 180 and 185 cm.

### 2.5.1 From histograms to continuous distributions

Examine the transition from a boxy hollow histogram in the top-left of Figure 2.26 to the much smoother plot in the lower-right. In this last plot, the bins are so slim that the hollow histogram is starting to resemble a smooth curve. This suggests the population height as a *continuous* numerical variable might best be explained by a curve that represents the outline of extremely slim bins.

This smooth curve represents a **probability density function** (also called a **density** or **distribution**), and such a curve is shown in Figure 2.28 overlaid on a histogram of the sample. A density has a special property: the total area under the density's curve is 1.

Figure 2.28: The continuous probability distribution of heights for US adults.

Figure 2.29: Density for heights in the US adult population with the area between 180 and 185 cm shaded. Compare this plot with Figure 2.27.

### 2.5.2 Probabilities from continuous distributions

We computed the proportion of individuals with heights 180 to 185 cm in Example 2.89 as a fraction:

$$\frac{\text{number of people between 180 and 185}}{\text{total sample size}}$$

We found the number of people with heights between 180 and 185 cm by determining the fraction of the histogram's area in this region. Similarly, we can use the area in the shaded region under the curve to find a probability (with the help of a computer):

$$P(\text{height between 180 and 185}) = \text{area between 180 and 185} = 0.1157$$

The probability that a randomly selected person is between 180 and 185 cm is 0.1157. This is very close to the estimate from Example 2.89: 0.1172.

- ⊙ **Exercise 2.90** Three US adults are randomly selected. The probability a single adult is between 180 and 185 cm is 0.1157.<sup>59</sup>

- (a) What is the probability that all three are between 180 and 185 cm tall?
- (b) What is the probability that none are between 180 and 185 cm?

- **Example 2.91** What is the probability that a randomly selected person is **exactly** 180 cm? Assume you can measure perfectly.

This probability is zero. A person might be close to 180 cm, but not exactly 180 cm tall. This also makes sense with the definition of probability as area; there is no area captured between 180 cm and 180 cm.

- ⊙ **Exercise 2.92** Suppose a person's height is rounded to the nearest centimeter. Is there a chance that a random person's **measured** height will be 180 cm?<sup>60</sup>

<sup>59</sup>Brief answers: (a)  $0.1157 \times 0.1157 \times 0.1157 = 0.0015$ . (b)  $(1 - 0.1157)^3 = 0.692$

<sup>60</sup>This has positive probability. Anyone between 179.5 cm and 180.5 cm will have a *measured* height of 180 cm. This is probably a more realistic scenario to encounter in practice versus Example 2.91.

## 2.6 Exercises

### 2.6.1 Defining probability

**2.1 True or false.** Determine if the statements below are true or false, and explain your reasoning.

- (a) If a fair coin is tossed many times and the last eight tosses are all heads, then the chance that the next toss will be heads is somewhat less than 50%.
- (b) Drawing a face card (jack, queen, or king) and drawing a red card from a full deck of playing cards are mutually exclusive events.
- (c) Drawing a face card and drawing an ace from a full deck of playing cards are mutually exclusive events.

**2.2 Roulette wheel.** The game of roulette involves spinning a wheel with 38 slots: 18 red, 18 black, and 2 green. A ball is spun onto the wheel and will eventually land in a slot, where each slot has an equal chance of capturing the ball.<sup>61</sup>

- (a) You watch a roulette wheel spin 3 consecutive times and the ball lands on a red slot each time. What is the probability that the ball will land on a red slot on the next spin?
- (b) You watch a roulette wheel spin 300 consecutive times and the ball lands on a red slot each time. What is the probability that the ball will land on a red slot on the next spin?
- (c) Are you equally confident of your answers to parts (a) and (b)? Why or why not?

**2.3 Four games, one winner.** Below are four versions of the same game. Your archnemesis gets to pick the version of the game, and then you get to choose how many times to flip a coin: 10 times or 100 times. Identify how many coin flips you should choose for each version of the game. It costs \$1 to play each game. Explain your reasoning.

- (a) If the proportion of heads is larger than 0.60, you win \$1.
- (b) If the proportion of heads is larger than 0.40, you win \$1.
- (c) If the proportion of heads is between 0.40 and 0.60, you win \$1.
- (d) If the proportion of heads is smaller than 0.30, you win \$1.

**2.4 Backgammon.** Backgammon is a board game for two players in which the playing pieces are moved according to the roll of two dice. Players win by removing all of their pieces from the board, so it is usually good to roll high numbers. You are playing backgammon with a friend and you roll two 6s in your first roll and two 6s in your second roll. Your friend rolls two 3s in his first roll and again in his second row. Your friend claims that you are cheating, because rolling double 6s twice in a row is very unlikely. Using probability, show that your rolls were just as likely as his.

**2.5 Coin flips.** If you flip a fair coin 10 times, what is the probability of

- (a) getting all tails?
- (b) getting all heads?
- (c) getting at least one tails?

**2.6 Dice rolls.** If you roll a pair of fair dice, what is the probability of

- (a) getting a sum of 1?
- (b) getting a sum of 5?
- (c) getting a sum of 12?

<sup>61</sup>Photo by Håkan Dahlström on Flickr, Roulette wheel.

**2.7 Swing voters.** A 2012 Pew Research survey asked 2,373 randomly sampled registered voters their political affiliation (Republican, Democrat, or Independent) and whether or not they identify as swing voters. 35% of respondents identified as Independent, 23% identified as swing voters, and 11% identified as both.<sup>62</sup>

- (a) Are being Independent and being a swing voter disjoint, i.e. mutually exclusive?
- (b) Draw a Venn diagram summarizing the variables and their associated probabilities.
- (c) What percent of voters are Independent but not swing voters?
- (d) What percent of voters are Independent or swing voters?
- (e) What percent of voters are neither Independent nor swing voters?
- (f) Is the event that someone is a swing voter independent of the event that someone is a political Independent?

**2.8 Poverty and language.** The American Community Survey is an ongoing survey that provides data every year to give communities the current information they need to plan investments and services. The 2010 American Community Survey estimates that 14.6% of Americans live below the poverty line, 20.7% speak a language other than English at home, and 4.2% fall into both categories.<sup>63</sup>

- (a) Are living below the poverty line and speaking a language other than English at home disjoint?
- (b) Draw a Venn diagram summarizing the variables and their associated probabilities.
- (c) What percent of Americans live below the poverty line and only speak English at home?
- (d) What percent of Americans live below the poverty line or speak a language other than English at home?
- (e) What percent of Americans live above the poverty line and only speak English at home?
- (f) Is the event that someone lives below the poverty line independent of the event that the person speaks a language other than English at home?

**2.9 Disjoint vs. independent.** In parts (a) and (b), identify whether the events are disjoint, independent, or neither (events cannot be both disjoint and independent).

- (a) You and a randomly selected student from your class both earn A's in this course.
- (b) You and your class study partner both earn A's in this course.
- (c) If two events can occur at the same time, must they be dependent?

**2.10 Guessing on an exam.** In a multiple choice exam, there are 5 questions and 4 choices for each question (a, b, c, d). Nancy has not studied for the exam at all and decides to randomly guess the answers. What is the probability that:

- (a) the first question she gets right is the 5<sup>th</sup> question?
- (b) she gets all of the questions right?
- (c) she gets at least one question right?

---

<sup>62</sup>Pew Research Center, With Voters Focused on Economy, Obama Lead Narrows, data collected between April 4-15, 2012.

<sup>63</sup>U.S. Census Bureau, 2010 American Community Survey 1-Year Estimates, Characteristics of People by Language Spoken at Home.

**2.11 Educational attainment of couples.** The table below shows the distribution of education level attained by US residents by gender based on data collected during the 2010 American Community Survey.<sup>64</sup>

		<i>Gender</i>	
		Male	Female
<i>Highest education attained</i>	Less than 9th grade	0.07	0.13
	9th to 12th grade, no diploma	0.10	0.09
	High school graduate, GED, or alternative	0.30	0.20
	Some college, no degree	0.22	0.24
	Associate's degree	0.06	0.08
	Bachelor's degree	0.16	0.17
	Graduate or professional degree	0.09	0.09
Total		1.00	1.00

- What is the probability that a randomly chosen man has at least a Bachelor's degree?
- What is the probability that a randomly chosen woman has at least a Bachelor's degree?
- What is the probability that a man and a woman getting married both have at least a Bachelor's degree? Note any assumptions you must make to answer this question.
- If you made an assumption in part (c), do you think it was reasonable? If you didn't make an assumption, double check your earlier answer and then return to this part.

**2.12 School absences.** Data collected at elementary schools in DeKalb County, GA suggest that each year roughly 25% of students miss exactly one day of school, 15% miss 2 days, and 28% miss 3 or more days due to sickness.<sup>65</sup>

- What is the probability that a student chosen at random doesn't miss any days of school due to sickness this year?
- What is the probability that a student chosen at random misses no more than one day?
- What is the probability that a student chosen at random misses at least one day?
- If a parent has two kids at a DeKalb County elementary school, what is the probability that neither kid will miss any school? Note any assumption you must make to answer this question.
- If a parent has two kids at a DeKalb County elementary school, what is the probability that that both kids will miss some school, i.e. at least one day? Note any assumption you make.
- If you made an assumption in part (d) or (e), do you think it was reasonable? If you didn't make any assumptions, double check your earlier answers.

**2.13 Grade distributions.** Each row in the table below is a proposed grade distribution for a class. Identify each as a valid or invalid probability distribution, and explain your reasoning.

	<i>Grades</i>				
	A	B	C	D	F
(a)	0.3	0.3	0.3	0.2	0.1
(b)	0	0	1	0	0
(c)	0.3	0.3	0.3	0	0
(d)	0.3	0.5	0.2	0.1	-0.1
(e)	0.2	0.4	0.2	0.1	0.1
(f)	0	-0.1	1.1	0	0

<sup>65</sup>S.S. Mizan et al. "Absence, Extended Absence, and Repeat Tardiness Related to Asthma Status among Elementary School Children". In: *Journal of Asthma* 48.3 (2011), pp. 228–234.

**2.14 Weight and health coverage, Part I.** The Behavioral Risk Factor Surveillance System (BRFSS) is an annual telephone survey designed to identify risk factors in the adult population and report emerging health trends. The following table summarizes two variables for the respondents: weight status using body mass index (BMI) and health coverage, which describes whether each respondent had health insurance.<sup>66</sup>

		<i>Weight Status</i>			Total
		Neither overweight nor obese (BMI < 25)	Overweight ( $25 \leq \text{BMI} < 30$ )	Obese (BMI $\geq 30$ )	
<i>Health Coverage</i>	Yes	134,801	141,699	107,301	383,801
	No	15,098	15,327	14,412	44,837
	Total	149,899	157,026	121,713	428,638

- (a) If we draw one individual at random, what is the probability that the respondent is overweight and doesn't have health coverage?
- (b) If we draw one individual at random, what is the probability that the respondent is overweight or doesn't have health coverage?

## 2.6.2 Conditional probability

**2.15 Joint and conditional probabilities.**  $P(A) = 0.3$ ,  $P(B) = 0.7$

- (a) Can you compute  $P(A \text{ and } B)$  if you only know  $P(A)$  and  $P(B)$ ?
- (b) Assuming that events A and B arise from independent random processes,
  - i. what is  $P(A \text{ and } B)$ ?
  - ii. what is  $P(A \text{ or } B)$ ?
  - iii. what is  $P(A|B)$ ?
- (c) If we are given that  $P(A \text{ and } B) = 0.1$ , are the random variables giving rise to events A and B independent?
- (d) If we are given that  $P(A \text{ and } B) = 0.1$ , what is  $P(A|B)$ ?

**2.16 PB & J.** Suppose 80% of people like peanut butter, 89% like jelly, and 78% like both. Given that a randomly sampled person likes peanut butter, what's the probability that he also likes jelly?

**2.17 Global warming.** A 2010 Pew Research poll asked 1,306 Americans "From what you've read and heard, is there solid evidence that the average temperature on earth has been getting warmer over the past few decades, or not?". The table below shows the distribution of responses by party and ideology, where the counts have been replaced with relative frequencies.<sup>67</sup>

		<i>Response</i>			Total
		Earth is warming	Not warming	Don't Know Refuse	
<i>Party and Ideology</i>	Conservative Republican	0.11	0.20	0.02	0.33
	Mod/Lib Republican	0.06	0.06	0.01	0.13
	Mod/Cons Democrat	0.25	0.07	0.02	0.34
	Liberal Democrat	0.18	0.01	0.01	0.20
Total		0.60	0.34	0.06	1.00

<sup>66</sup>Office of Surveillance, Epidemiology, and Laboratory Services Behavioral Risk Factor Surveillance System, BRFSS 2010 Survey Data.

<sup>67</sup>Pew Research Center, Majority of Republicans No Longer See Evidence of Global Warming, data collected on October 27, 2010.

- What is the probability that a randomly chosen respondent believes the earth is warming or is a liberal Democrat?
- What is the probability that a randomly chosen respondent believes the earth is warming given that he is a liberal Democrat?
- What is the probability that a randomly chosen respondent believes the earth is warming given that he is a conservative Republican?
- Does it appear that whether or not a respondent believes the earth is warming is independent of their party and ideology? Explain your reasoning.
- What is the probability that a randomly chosen respondent is a moderate/liberal Republican given that he does not believe that the earth is warming?

**2.18 Weight and health coverage, Part II.** Exercise 2.14 introduced a contingency table summarizing the relationship between weight status, which is determined based on body mass index (BMI), and health coverage for a sample of 428,638 Americans. In the table below, the counts have been replaced by relative frequencies (probability estimates).

		<i>Weight Status</i>			Total
		Neither overweight nor obese (BMI < 25)	Overweight (25 ≤ BMI < 30)	Obese (BMI ≥ 30)	
<i>Health Coverage</i>	Yes	0.3145	0.3306	0.2503	0.8954
	No	0.0352	0.0358	0.0336	0.1046
	Total	0.3497	0.3664	0.2839	1.0000

- What is the probability that a randomly chosen individual is obese?
- What is the probability that a randomly chosen individual is obese given that he has health coverage?
- What is the probability that a randomly chosen individual is obese given that he doesn't have health coverage?
- Do being overweight and having health coverage appear to be independent?

**2.19 Burger preferences.** A 2010 SurveyUSA poll asked 500 Los Angeles residents, "What is the best hamburger place in Southern California? Five Guys Burgers? In-N-Out Burger? Fat Burger? Tommy's Hamburgers? Umami Burger? Or somewhere else?" The distribution of responses by gender is shown below.<sup>68</sup>

		<i>Gender</i>		Total
		Male	Female	
<i>Best hamburger place</i>	Five Guys Burgers	5	6	11
	In-N-Out Burger	162	181	343
	Fat Burger	10	12	22
	Tommy's Hamburgers	27	27	54
	Umami Burger	5	1	6
	Other	26	20	46
	Not Sure	13	5	18
	Total	248	252	500

- What is the probability that a randomly chosen male likes In-N-Out the best?
- What is the probability that a randomly chosen female likes In-N-Out the best?
- What is the probability that a man and a woman who are dating both like In-N-Out the best? Note any assumption you make and evaluate whether you think that assumption is reasonable.
- What is the probability that a randomly chosen person likes Umami best or that person is female?

<sup>68</sup>SurveyUSA, Results of SurveyUSA News Poll #17718, data collected on December 2, 2010.

**2.20 Assortative mating.** Assortative mating is a nonrandom mating pattern where individuals with similar genotypes and/or phenotypes mate with one another more frequently than what would be expected under a random mating pattern. Researchers studying this topic collected data on eye colors of 204 Scandinavian men and their female partners. The table below summarizes the results. For simplicity, we only include heterosexual relationships in this exercise.<sup>69</sup>

		<i>Partner (female)</i>			Total
		Blue	Brown	Green	
<i>Self (male)</i>	Blue	78	23	13	114
	Brown	19	23	12	54
	Green	11	9	16	36
	Total	108	55	41	204

- What is the probability that a randomly chosen male respondent or his partner has blue eyes?
- What is the probability that a randomly chosen male respondent with blue eyes has a partner with blue eyes?
- What is the probability that a randomly chosen male respondent with brown eyes has a partner with blue eyes? What about the probability of a randomly chosen male respondent with green eyes having a partner with blue eyes?
- Does it appear that the eye colors of male respondents and their partners are independent? Explain your reasoning.

**2.21 Drawing box plots.** After an introductory statistics course, 80% of students can successfully construct box plots. Of those who can construct box plots, 86% passed, while only 65% of those students who could not construct box plots passed.

- Construct a tree diagram of this scenario.
- Calculate the probability that a student is able to construct a box plot if it is known that he passed.

**2.22 Predisposition for thrombosis.** A genetic test is used to determine if people have a predisposition for *thrombosis*, which is the formation of a blood clot inside a blood vessel that obstructs the flow of blood through the circulatory system. It is believed that 3% of people actually have this predisposition. The genetic test is 99% accurate if a person actually has the predisposition, meaning that the probability of a positive test result when a person actually has the predisposition is 0.99. The test is 98% accurate if a person does not have the predisposition. What is the probability that a randomly selected person who tests positive for the predisposition by the test actually has the predisposition?

**2.23 HIV in Swaziland.** Swaziland has the highest HIV prevalence in the world: 25.9% of this country's population is infected with HIV.<sup>70</sup> The ELISA test is one of the first and most accurate tests for HIV. For those who carry HIV, the ELISA test is 99.7% accurate. For those who do not carry HIV, the test is 92.6% accurate. If an individual from Swaziland has tested positive, what is the probability that he carries HIV?

**2.24 Exit poll.** Edison Research gathered exit poll results from several sources for the Wisconsin recall election of Scott Walker. They found that 53% of the respondents voted in favor of Scott Walker. Additionally, they estimated that of those who did vote in favor for Scott Walker, 37% had a college degree, while 44% of those who voted against Scott Walker had a college degree. Suppose we randomly sampled a person who participated in the exit poll and found that he had a college degree. What is the probability that he voted in favor of Scott Walker?<sup>71</sup>

<sup>69</sup>B. Laeng et al. "Why do blue-eyed men prefer women with the same eye color?" In: *Behavioral Ecology and Sociobiology* 61.3 (2007), pp. 371–384.

<sup>70</sup>Source: CIA Factbook, Country Comparison: HIV/AIDS - Adult Prevalence Rate.

<sup>71</sup>New York Times, Wisconsin recall exit polls.

**2.25 It's never lupus.** Lupus is a medical phenomenon where antibodies that are supposed to attack foreign cells to prevent infections instead see plasma proteins as foreign bodies, leading to a high risk of blood clotting. It is believed that 2% of the population suffer from this disease. The test is 98% accurate if a person actually has the disease. The test is 74% accurate if a person does not have the disease.

There is a line from the Fox television show *House* that is often used after a patient tests positive for lupus: "It's never lupus." Do you think there is truth to this statement? Use appropriate probabilities to support your answer.

**2.26 Twins.** About 30% of human twins are identical, and the rest are fraternal. Identical twins are necessarily the same sex – half are males and the other half are females. One-quarter of fraternal twins are both male, one-quarter both female, and one-half are mixes: one male, one female. You have just become a parent of twins and are told they are both girls. Given this information, what is the probability that they are identical?

### 2.6.3 Sampling from a small population

**2.27 Urns and marbles, Part I.** Imagine you have an urn containing 5 red, 3 blue, and 2 orange marbles in it.

- (a) What is the probability that the first marble you draw is blue?
- (b) Suppose you drew a blue marble in the first draw. If drawing with replacement, what is the probability of drawing a blue marble in the second draw?
- (c) Suppose you instead drew an orange marble in the first draw. If drawing with replacement, what is the probability of drawing a blue marble in the second draw?
- (d) If drawing with replacement, what is the probability of drawing two blue marbles in a row?
- (e) When drawing with replacement, are the draws independent? Explain.

**2.28 Socks in a drawer.** In your sock drawer you have 4 blue, 5 gray, and 3 black socks. Half asleep one morning you grab 2 socks at random and put them on. Find the probability you end up wearing

- (a) 2 blue socks
- (b) no gray socks
- (c) at least 1 black sock
- (d) a green sock
- (e) matching socks

**2.29 Urns and marbles, Part II.** Imagine you have an urn containing 5 red, 3 blue, and 2 orange marbles.

- (a) Suppose you draw a marble and it is blue. If drawing without replacement, what is the probability the next is also blue?
- (b) Suppose you draw a marble and it is orange, and then you draw a second marble without replacement. What is the probability this second marble is blue?
- (c) If drawing without replacement, what is the probability of drawing two blue marbles in a row?
- (d) When drawing without replacement, are the draws independent? Explain.

**2.30 Books on a bookshelf.** The table below shows the distribution of books on a bookcase based on whether they are nonfiction or fiction and hardcover or paperback.

	<i>Format</i>		Total
	Hardcover	Paperback	
<i>Type</i>	Fiction	13	59
	Nonfiction	15	8
	Total	28	67
			95

- Find the probability of drawing a hardcover book first then a paperback fiction book second when drawing without replacement.
- Determine the probability of drawing a fiction book first and then a hardcover book second, when drawing without replacement.
- Calculate the probability of the scenario in part (b), except this time complete the calculations under the scenario where the first book is placed back on the bookcase before randomly drawing the second book.
- The final answers to parts (b) and (c) are very similar. Explain why this is the case.

**2.31 Student outfits.** In a classroom with 24 students, 7 students are wearing jeans, 4 are wearing shorts, 8 are wearing skirts, and the rest are wearing leggings. If we randomly select 3 students without replacement, what is the probability that one of the selected students is wearing leggings and the other two are wearing jeans? Note that these are mutually exclusive clothing options.

**2.32 The birthday problem.** Suppose we pick three people at random. For each of the following questions, ignore the special case where someone might be born on February 29th, and assume that births are evenly distributed throughout the year.

- What is the probability that the first two people share a birthday?
- What is the probability that at least two people share a birthday?

## 2.6.4 Random variables

**2.33 College smokers.** At a university, 13% of students smoke.

- Calculate the expected number of smokers in a random sample of 100 students from this university.
- The university gym opens at 9am on Saturday mornings. One Saturday morning at 8:55am there are 27 students outside the gym waiting for it to open. Should you use the same approach from part (a) to calculate the expected number of smokers among these 27 students?

**2.34 Card game.** Consider the following card game with a well-shuffled deck of cards. If you draw a red card, you win nothing. If you get a spade, you win \$5. For any club, you win \$10 plus an extra \$20 for the ace of clubs.

- Create a probability model for the amount you win at this game. Also, find the expected winnings for a single game and the standard deviation of the winnings.
- What is the maximum amount you would be willing to pay to play this game? Explain.

**2.35 Another card game.** In a new card game, you start with a well-shuffled full deck and draw 3 cards without replacement. If you draw 3 hearts, you win \$50. If you draw 3 black cards, you win \$25. For any other draws, you win nothing.

- Create a probability model for the amount you win at this game, and find the expected winnings. Also compute the standard deviation of this distribution.
- If the game costs \$5 to play, what would be the expected value and standard deviation of the net profit (or loss)? (*Hint: profit = winnings - cost;  $X - 5$* )
- If the game costs \$5 to play, should you play this game? Explain.

**2.36 Is it worth it?** Andy is always looking for ways to make money fast. Lately, he has been trying to make money by gambling. Here is the game he is considering playing: The game costs \$2 to play. He draws a card from a deck. If he gets a number card (2-10), he wins nothing. For any face card (jack, queen or king), he wins \$3. For any ace, he wins \$5, and he wins an *extra* \$20 if he draws the ace of clubs.

- Create a probability model and find Andy's expected profit per game.
- Would you recommend this game to Andy as a good way to make money? Explain.

**2.37 Portfolio return.** A portfolio's value increases by 18% during a financial boom and by 9% during normal times. It decreases by 12% during a recession. What is the expected return on this portfolio if each scenario is equally likely?

**2.38 A game of roulette, Part I.** The game of roulette involves spinning a wheel with 38 slots: 18 red, 18 black, and 2 green. A ball is spun onto the wheel and will eventually land in a slot, where each slot has an equal chance of capturing the ball. Gamblers can place bets on red or black. If the ball lands on their color, they double their money. If it lands on another color, they lose their money. Suppose you bet \$1 on red. What's the expected value and standard deviation of your winnings?

**2.39 A game of roulette, Part II.** Exercise 2.38 describes winnings on a game of roulette.

- Suppose you play roulette and bet \$3 on a single round. What is the expected value and standard deviation of your total winnings?
- Suppose you bet \$1 in three different rounds. What is the expected value and standard deviation of your total winnings?
- How do your answers to parts (a) and (b) compare? What does this say about the riskiness of the two games?

**2.40 Baggage fees.** An airline charges the following baggage fees: \$25 for the first bag and \$35 for the second. Suppose 54% of passengers have no checked luggage, 34% have one piece of checked luggage and 12% have two pieces. We suppose a negligible portion of people check more than two bags.

- Build a probability model, compute the average revenue per passenger, and compute the corresponding standard deviation.
- About how much revenue should the airline expect for a flight of 120 passengers? With what standard deviation? Note any assumptions you make and if you think they are justified.

**2.41 Dodgers vs. Padres.** You and your friend decide to bet on the Major League Baseball game happening one evening between the Los Angeles Dodgers and the San Diego Padres. Suppose current statistics indicate that the Dodgers have a 0.46 probability of winning this game against the Padres. If your friend bets you \$5 that the Dodgers will win, how much would you need to bet on the Padres to make this a fair game?

**2.42 Selling on Ebay.** Marcie has been tracking the following two items on Ebay:

- A textbook that sells for an average of \$110 with a standard deviation of \$4.
  - Mario Kart for the Nintendo Wii, which sells for an average of \$38 with a standard deviation of \$5.
- Marcie wants to sell the video game and buy the textbook. How much net money (profits - losses) would she expect to make or spend? Also compute the standard deviation of how much she would make or spend.
  - Lucy is selling the textbook on Ebay for a friend, and her friend is giving her a 10% commission (Lucy keeps 10% of the revenue). How much money should she expect to make? With what standard deviation?

**2.43 Cost of breakfast.** Sally gets a cup of coffee and a muffin every day for breakfast from one of the many coffee shops in her neighborhood. She picks a coffee shop each morning at random and independently of previous days. The average price of a cup of coffee is \$1.40 with a standard deviation of 30¢(\$0.30), the average price of a muffin is \$2.50 with a standard deviation of 15¢, and the two prices are independent of each other.

- What is the mean and standard deviation of the amount she spends on breakfast daily?
- What is the mean and standard deviation of the amount she spends on breakfast weekly (7 days)?

**2.44 Ice cream.** Ice cream usually comes in 1.5 quart boxes (48 fluid ounces), and ice cream scoops hold about 2 ounces. However, there is some variability in the amount of ice cream in a box as well as the amount of ice cream scooped out. We represent the amount of ice cream in the box as  $X$  and the amount scooped out as  $Y$ . Suppose these random variables have the following means, standard deviations, and variances:

	mean	SD	variance
$X$	48	1	1
$Y$	2	0.25	0.0625

- An entire box of ice cream, plus 3 scoops from a second box is served at a party. How much ice cream do you expect to have been served at this party? What is the standard deviation of the amount of ice cream served?
- How much ice cream would you expect to be left in the box after scooping out one scoop of ice cream? That is, find the expected value of  $X - Y$ . What is the standard deviation of the amount left in the box?
- Using the context of this exercise, explain why we add variances when we subtract one random variable from another.

### 2.6.5 Continuous distributions

**2.45 Cat weights.** The histogram shown below represents the weights (in kg) of 47 female and 97 male cats.<sup>72</sup>

- What fraction of these cats weigh less than 2.5 kg?
- What fraction of these cats weigh between 2.5 and 2.75 kg?
- What fraction of these cats weigh between 2.75 and 3.5 kg?

<sup>72</sup>W. N. Venables and B. D. Ripley. *Modern Applied Statistics with S*. Fourth Edition. <http://www.stats.ox.ac.uk/pub/MASS4>. New York: Springer, 2002.

**2.46 Income and gender.** The relative frequency table below displays the distribution of annual total personal income (in 2009 inflation-adjusted dollars) for a representative sample of 96,420,486 Americans. These data come from the American Community Survey for 2005-2009. This sample is comprised of 59% males and 41% females.<sup>73</sup>

	<i>Income</i>	<i>Total</i>
(a) Describe the distribution of total personal income.	\$1 to \$9,999 or loss	2.2%
(b) What is the probability that a randomly chosen US resident makes less than \$50,000 per year?	\$10,000 to \$14,999	4.7%
(c) What is the probability that a randomly chosen US resident makes less than \$50,000 per year and is female? Note any assumptions you make.	\$15,000 to \$24,999	15.8%
	\$25,000 to \$34,999	18.3%
	\$35,000 to \$49,999	21.2%
(d) The same data source indicates that 71.8% of females make less than \$50,000 per year. Use this value to determine whether or not the assumption you made in part (c) is valid.	\$50,000 to \$64,999	13.9%
	\$65,000 to \$74,999	5.8%
	\$75,000 to \$99,999	8.4%
	\$100,000 or more	9.7%

<sup>73</sup>U.S. Census Bureau, 2005-2009 American Community Survey.
